

- The diagram below shows the general trend for the first ionisation energy for some *s* and *p* block elements.

How will the general trend differ for the second ionisation energy of these elements (*i.e.*  $X^+(g) \rightarrow X^{2+}(g) + e^-$ )? Explain.

**The second ionisation of Na will be off the scale as a core electron is ionised. (Actual value > 4500 kJ mol<sup>-1</sup>)**

**Mg<sup>+</sup> is isoelectronic with Na, Al<sup>+</sup> is isoelectronic with Mg, *etc.*, so the second ionisations of the other elements follow the same trends as the first ionisations (for exactly the same reasons), but displaced one atomic number to the right and at a slightly higher energy (as  $Z_{\text{eff}}$  is greater).**
