

- Name the two intermolecular forces, which best explain the difference in boiling points of 1-propanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ; bp = 97.2 °C) and 1-propanethiol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{SH}$ ; bp = 67.8 °C).

**H-bonding is dominant and strong in  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  due to the electronegativity of oxygen. The lower electronegativity of sulfur ensures that H-bonding is quite weak in  $\text{CH}_3\text{CH}_2\text{CH}_2\text{SH}$  and weaker dipole-dipole interactions are probably more important.**

**The alkyl chain in both will interact via dispersion forces, but these are likely to be similar in both systems.**

- Consider the boiling points of the compounds 1-propanol, 1-propanethiol and 1-propaneselenol shown in the table below?

Compound	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> OH	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> SH	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> SeH
Boiling point (° C)	97.2	67.8	147.0

With reference to intermolecular forces, explain briefly why the boiling points increase in the order CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>SH < CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>OH < CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>SeH.

**Polarisability of atoms increases as the size of the atoms increase. The greater the polarisability, the stronger the dispersion forces. On this basis, the expected boiling point order would be C<sub>3</sub>H<sub>7</sub>OH < C<sub>3</sub>H<sub>7</sub>SH < C<sub>3</sub>H<sub>7</sub>SeH.**

**C<sub>3</sub>H<sub>7</sub>OH also has hydrogen bonding between the OH groups. H-bonding is a stronger intermolecular force than dispersion forces and this increases the boiling point of C<sub>3</sub>H<sub>7</sub>OH to be above that of C<sub>3</sub>H<sub>7</sub>SH. The effect is not enough to push it above the boiling point of C<sub>3</sub>H<sub>7</sub>SeH.**

- Hydrogen bond strength increases in the order  $\text{N-H}\cdots\text{N} < \text{O-H}\cdots\text{O} < \text{F-H}\cdots\text{F}$ . Use this information and the data given in the table to explain the differences in boiling point of ammonia, water and hydrogen fluoride.

Compound	$\text{NH}_3$	$\text{H}_2\text{O}$	HF
Boiling point / $^{\circ}\text{C}$	-33	100	20

**$\text{NH}_3$  and HF both have two H-bond per molecule and their boiling points are in the expected order - HF has the stronger H-bonds and the higher boiling point.**

**$\text{H}_2\text{O}$  has 4 H-bonds per molecule, so although the bonds are not as strong as those of HF, there are twice as many of them. As a result the boiling point of  $\text{H}_2\text{O}$  is greater than that of HF.**
