

If 0.250 mol of HI(g) is introduced into a 2.00 L flask at 700 °C, what will be the concentration of I<sub>2</sub>(g) at equilibrium?

The initial concentration of HI(g) is  $0.250 / 2.00 \text{ mol L}^{-1} = 0.125 \text{ mol L}^{-1}$ .

	H <sub>2</sub> (g)	I <sub>2</sub> (g)	$\rightleftharpoons$	2HI(g)
<b>Initial</b>	<b>0</b>	<b>0</b>		<b>0.125</b>
<b>Change</b>	<b>+x</b>	<b>+x</b>		<b>-2x</b>
<b>Equilibrium</b>	<b>x</b>	<b>x</b>		<b>0.125 - 2x</b>

Thus,

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(0.125 - 2x)^2}{(x)(x)} = \frac{(0.125 - 2x)^2}{x^2} = 49.0 \text{ (from 2008-N-5)}$$

$$(49.0)^{1/2} = \frac{(0.125 - 2x)}{x}$$

Rearranging gives  $x = [\text{I}_2(\text{g})] = 0.0139 \text{ M}$ .

Answer: **0.0139 M**

If 0.274 g of H<sub>2</sub>S were now introduced into the same flask, what would be the concentration of S<sub>2</sub>(g) at equilibrium?

The molar mass of H<sub>2</sub>S is  $(2 \times 1.008 \text{ (H)} + 32.06 \text{ (S)}) = 34.08 \text{ g mol}^{-1}$ . Hence, 0.274 g of H<sub>2</sub>S corresponds to:

$$\begin{aligned} \text{number of moles} &= \text{mass} / \text{molar mass} \\ &= (0.274 \text{ g}) / (34.08 \text{ g mol}^{-1}) = 8.04 \times 10^{-3} \text{ mol} \end{aligned}$$

The initial concentration of H<sub>2</sub>S is thus  $8.04 \times 10^{-3} \text{ mol} / 2.00 \text{ M} = 4.02 \times 10^{-3} \text{ M}$ .

From above,  $[\text{I}_2(\text{g})] = 0.0139 \text{ M}$  and  $[\text{HI}(\text{g})] = (0.125 - 2 \times 0.0139) \text{ M} = 0.00972 \text{ M}$ .

Using the overall equilibrium reaction derived in 2008-N-5:

	2I <sub>2</sub> (g)	2H <sub>2</sub> S(g)	$\rightleftharpoons$	S <sub>2</sub> (g)	4HI(g)
<b>Initial</b>	<b>0.0139</b>	<b>0.00402</b>		<b>0</b>	<b>0.00972</b>
<b>Change</b>	<b>-2x</b>	<b>-2x</b>		<b>+x</b>	<b>+2x</b>
<b>Equilibrium</b>	<b>0.0139 - 2x</b>	<b>0.00402 - 2x</b>		<b>x</b>	<b>0.00972 + 4x</b>

ANSWER CONTINUES ON THE NEXT PAGE

Thus,

$$K_c = \frac{[\text{S}_2][\text{HI}]^4}{[\text{I}_2]^2[\text{I}_2]^2} = \frac{(x)(0.00972+4x)^4}{(0.0139-2x)^2(0.00402-2x)^2}$$
$$\sim \frac{(x)(0.00972)^4}{(0.0139)^2(0.00402)^2} = 2.23 \times 10^{-5} \text{ (from 2008-N-5)}$$

where the small  $x$  approximation has been used as  $K_c$  is so small. This gives:

$$x = [\text{S}_2(\text{g})] = 7.82 \times 10^{-10} \text{ M}$$

Answer:  $7.82 \times 10^{-10} \text{ M}$
