- Balance the following nuclear reactions by identifying the missing nuclear particle. nugget and what is its mass (in kg )?

One mole of gold corresponds to Avogadro's number, $\mathbf{6 . 0 2 2} \times \mathbf{1 0}^{\mathbf{2 3}}$, atoms. $2.6 \times 10^{24}$ atoms therefore corresponds to:

$$
\text { number of moles }=\frac{\text { number of atoms }}{\text { Avogadro's number }}=\frac{2.6 \times 10^{24}}{6.022 \times 10^{23}}=4.3 \mathrm{~mol}
$$

As one mole of gold has a mass, corresponding to the atomic mass, of 196.97 g . 4.3 mol of gold therefore corresponds to:

$$
\text { mass }=\text { number of moles } \times \text { atomic mass }=4.3 \times 196.97=850 \mathrm{~g}=0.85 \mathrm{~kg}
$$

(Note that the number of atoms is given to 2 significant figures in the question and this is reflected in the answers).

| Amount: $\mathbf{4 . 3} \mathbf{~ m o l}$ | Mass: $\mathbf{0 . 8 5} \mathbf{~ k g}$ |
| :--- | :--- |

- What element has the ground state electronic arrangement of $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{3}$ ?

## Phosphorus

- A mobile phone sends signals at about $850 \mathrm{MHz}\left(1 \mathrm{MHz}=1 \times 10^{6} \mathrm{~Hz}\right)$. What is the wavelength of this radiation?

The frequency, $v=850 \mathrm{MHz}=850 \times 10^{6} \mathrm{~Hz}$, is related to the wavelength, $\lambda$, by the equation:
$\mathbf{c}=\lambda \nu$ or $\lambda=\frac{\mathbf{c}}{v}$ where $\mathbf{c}$ is the speed of light.
Therefore, wavelength $=\lambda=\frac{2.998 \times 10^{8} \mathrm{~m} \mathrm{~s}^{-1}}{850 \times 10^{6} \mathrm{~m}}=0.35 \mathrm{~m}$

$$
\text { Wavelength }=0.35 \mathrm{~m}
$$

- Account for why solid metals can conduct an electric current, but solid ionic compounds cannot.

The crystal structure of a metal consists of a lattice of positively charged nuclei surrounded by a "sea of electrons". These electrons are free to move under the influence of an electric field so can conduct the current.

An ionic solid consists of a lattice of positive and negative ions, packed together to minimise repulsion and maximise attraction. The atomic nuclei are fixed in place and all the electrons are localised around them so they are unable to conduct the current (They can conduct current when molten as the ions are then free to move.)

- Complete the entries in the following table.

| Element name | Symbol | Mass <br> number | Atomic <br> number | Number of <br> electrons | Number of <br> neutrons | ${ }_{{ }_{z}}^{\mathrm{m}} \mathrm{X}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| lithium | $\mathbf{L i}$ | 7 | 3 | $\mathbf{3}$ | $\mathbf{4}$ | ${ }_{3}^{7} \mathbf{L i}$ |
| copper | $\mathbf{C u}$ | $\mathbf{6 4}$ | $\mathbf{2 9}$ | 29 | $\mathbf{3 5}$ | ${ }_{29}^{64} \mathbf{C u}$ |
| aluminium | $\mathbf{A l}$ | $\mathbf{2 7}$ | 13 | $\mathbf{1 3}$ | 14 | ${ }_{13}^{27} \mathbf{A l}$ |

- Give the formula and name of the binary compound formed from the following elements.

| lithium and oxygen | Formula | Name |
| :---: | :---: | :---: |
|  | $\mathbf{L i}_{2} \mathbf{O}$ | lithium oxide |
| calcium and hydrogen | $\mathrm{CaH}_{2}$ | calcium hydride |

- The complete combustion of propane, $\mathrm{C}_{3} \mathrm{H}_{8}$, in air gives water and carbon dioxide as the products? Write a balanced equation for this reaction.

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

What mass of oxygen is required for the complete combustion of 454 g of propane and what masses of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ are produced?

The molar mass of propane is $(3 \times 12.01(\mathrm{C}))+(8 \times 1.008(\mathrm{H}))=44.094$.
Therefore, $\mathbf{4 5 4} \mathrm{g}$ corresponds to:

$$
\text { number of moles }=\frac{\text { mass }}{\text { molar mass }}=\frac{454}{44.094}=10.3 \mathrm{~mol}
$$

5 mol of $\mathrm{O}_{2}(\mathrm{~g})$ is required for every 1 mol of propane. Therefore, $5 \times 10.3=51.5$ mol of $\mathrm{O}_{2}$ is required. The molar mass of $\mathrm{O}_{2}$ is $(2 \times 16.00)=32.00$ so the mass of $\mathrm{O}_{2}$ required is:

$$
\text { mass }=\text { number of moles } \times \text { molar mass }=51.5 \times 32.00=1650 \mathrm{~g}=1.65 \mathrm{~kg}
$$

3 mol of $\mathrm{CO}_{2}$ and $4 \mathbf{~ m o l}$ of $\mathrm{H}_{\mathbf{2}} \mathrm{O}$ are produced for every $\mathbf{1 ~ m o l}$ of propane.
 produced.

The molar mass of $\mathrm{CO}_{2}$ is $(\mathbf{1 2 . 0 1}(\mathrm{C}))+(2 \times 16.00(\mathrm{O}))=44.01$ and the molar mass of $\mathrm{H}_{2} \mathrm{O}$ is $(2 \times 1.008(\mathrm{H}))+(16.00(\mathrm{O}))=18.016$.

The masses of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ produced are therefore:

$$
\begin{aligned}
& \text { mass of } \mathrm{CO}_{2}=30.9 \times 44.01=1360 \mathrm{~g}=1.36 \mathrm{~kg} \\
& \text { mass of } \mathrm{H}_{2} \mathrm{O}=41.2 \times 18.016=742 \mathrm{~g}=0.742 \mathrm{~kg}
\end{aligned}
$$

(Note that the mass of propane is given to three significant figures in the question and this is reflected in each answer).

Explain the "law of conservation of mass". Show whether or not the above combustion conforms to this law.

The law of conservation of mass states that mass may neither be created nor destroyed. In this reaction:

```
mass of reactants = 0.454 kg (C3 (H8) + 1.65 kg (O2) = 2.10 kg
mass of products = 1.36 kg(CO
```

This combustion obeys the law (to 3 significant figures).

- The reaction of methane and water is one way to prepare hydrogen for use as a fuel.

$$
\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightarrow \mathrm{CO}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})
$$

Which compound is the limiting reactant if you begin with 995 g of methane and 2510 g of water?

The molar mass of methane, $\mathrm{CH}_{4}$, is $(12.01(\mathrm{C}))+(4 \times 1.008(\mathrm{H}))=16.042$. The number of moles of methane is therefore:

$$
\text { moles of methane }=\frac{\text { mass }}{\text { molar mass }}=\frac{995}{16.042}=62.0 \mathrm{~mol}
$$

The molar mass of water, $\mathrm{H}_{2} \mathrm{O}$, is $(2 \times 1.008(\mathrm{H}))+(16.00(\mathrm{H}))=18.016$. The number of moles of water is therefore:

$$
\text { moles of methane }=\frac{\text { mass }}{\text { molar mass }}=\frac{2510}{18.016}=139 \mathrm{~mol}
$$

As the reaction is a $1: 1$ reaction of methane and water, methane is the limiting reagent.

## Answer: methane, $\mathbf{C H}_{4}$

What mass of the excess reactant remains when the reaction is completed?

As the reaction is a $1: 1$ reaction, $(\mathbf{1 3 9}-\mathbf{6 2 . 0})=\mathbf{7 7} \mathbf{~ m o l}$ of $\mathrm{H}_{\mathbf{2}} \mathrm{O}$ will be left unreacted. This corresponds to a mass of:
mass of water $=$ moles of water $\times$ molar mass $=77 \times 18.016=1400 \mathrm{~g}=1.4 \mathrm{~kg}$.

Answer: $\mathbf{1 . 4 ~ k g}$

- An unknown compound contains carbon and hydrogen only. If 0.0956 g of the compound is burned in oxygen, 0.300 g of $\mathrm{CO}_{2}$ and 0.123 g of $\mathrm{H}_{2} \mathrm{O}$ are isolated. What is the unknown compound's empirical formula?

The molar mass of $\mathrm{CO}_{2}$ is $(12.01(\mathrm{C}))+(2 \times 16.00(\mathrm{O}))=44.01$. The molar mass of $\mathrm{H}_{2} \mathrm{O}$ is $(2 \times 1.008(\mathrm{H}))+(\mathbf{1 6 . 0 0}(\mathrm{O}))=18.016$. The number of moles of each after burning is therefore:

$$
\mathbf{n}_{\mathrm{CO}_{2}}=\frac{\text { mass }}{\text { molar mass }}=\frac{0.300}{44.01}=0.00682 \mathrm{~mol}, \mathbf{n}_{\mathbf{H}_{2} \mathrm{O}}=\frac{0.123}{18.016}=0.00683 \mathrm{~mol}
$$

The moles of C in the compound is equal to the number of moles of $\mathrm{CO}_{2}$, as the latter possesses one carbon atom per molecular unit.

The moles of H in the compound is equal to $2 \times$ number of moles of $\mathrm{H}_{2} \mathrm{O}$, as the latter contains two hydrogen atoms per molecular unit.

The $\mathbf{C}: \mathbf{H}$ ratio is therefore 1:2

## Answer: $\mathbf{C H}_{2}$

If its molar mass is found to be $70.1 \mathrm{~g} \mathrm{~mol}^{-1}$, what is its molecular formula?

If the molar mass $=70.1$, the number of moles in 0.0956 g is:

$$
\text { number of moles }=\frac{\text { mass }}{\text { molar mass }}=\frac{0.0956}{70.1}=0.00136 \mathrm{~mol}
$$

As 0.00136 mol contains 0.683 mol of carbon, 1 mol contains $\frac{0.00683}{0.00136}=5.01 \mathrm{~mol}$
As $\mathbf{C}: H$ is $\mathbf{1 : 2}$, the compound must contain 10 hydrogen atoms.

Answer: $\mathbf{C}_{\mathbf{5}} \mathbf{H}_{\mathbf{1 0}}$

- What amount (in mol) of chloride ion is contained in 100 mL of 0.25 M magnesium chloride solution?

Magnesium chloride dissolves according to the equation, $\mathbf{M g C l}_{\mathbf{2}}(\mathrm{s}) \rightarrow \mathbf{M g}^{\mathbf{2}}(\mathbf{a q})+$ $2 \mathrm{Cl}^{-}(\mathrm{aq})$ so that two moles of chloride is produced for every mole of $\mathbf{M g C l}_{\mathbf{2}}$ present. The number of moles of $\mathbf{M g C l}_{\mathbf{2}}$ present is :
number of moles $=$ concentration $\times$ volume $=0.25 \times \frac{100}{1000}=0.025 \mathrm{~mol}$

The number of moles of $\mathrm{Cl}^{-}(\mathrm{aq})$ is therefore $2 \times 0.025=0.050 \mathrm{~mol}$

Answer: $\mathbf{0 . 0 5 0} \mathbf{~ m o l}$

- If 25.0 mL of 1.50 M hydrochloric acid is diluted to 500 mL , what is the molar concentration of the diluted acid?

The number of moles of $\mathbf{H C l}$ present in $\mathbf{2 5 . 0} \mathbf{~ m L}$ of a $\mathbf{1 . 5 0} \mathbf{M}$ solution is:

$$
\text { number of moles }=\text { concentration } \times \text { volume }=1.50 \times \frac{25}{1000}=0.0375 \mathrm{~mol}
$$

This number of moles in a $\mathbf{5 0 0} \mathbf{~ m L}$ solution gives a concentration of:

$$
\text { concentration }=\frac{\text { number of moles }}{\text { volume }}=\frac{0.0375}{(500 / 1000)}=0.0750 \mathrm{M}
$$

- A 1.00 g sample of ammonium nitrate, $\mathrm{NH}_{4} \mathrm{NO}_{3}$, is decomposed in a bomb calorimeter causing the temperature of the calorimeter to increase by 6.12 K . The heat capacity of the system is $1.23 \mathrm{~kJ}^{\circ} \mathrm{C}^{-1}$.

Describe this process as either endothermic or exothermic.
exothermic

What is the molar heat of decomposition for ammonium nitrate?

The heat change is given by $q=C \times \Delta T=1.23 \times 6.12=7.53 \mathrm{~kJ}$. As the reaction is exothermic, the heat of decomposition for 1.00 g of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ is $\Delta \mathrm{H}=-7.53 \mathrm{~kJ}$.

The molar mass of $\mathbf{N H}_{4} \mathbf{N O}_{3}$ is:

$$
\text { molar mass }=(2 \times 14.01(\mathrm{~N}))+(4 \times 1.008(\mathrm{H}))+(3 \times 16.00(\mathrm{O}))=80.052
$$

1.000 g therefore corresponds to $\frac{1.000}{80.052}=\mathbf{0 . 0 1 2 5} \mathrm{mol}$. The molar heat of decomposition is then: $\Delta H=\frac{-7.53}{0.0125}=-602 \mathrm{~kJ} \mathrm{~mol}^{-1}$

Answer: -602 kJ mol ${ }^{\mathbf{1}}$

- Heating $\mathrm{SbCl}_{5}$ causes it to decompose according to the following equation.

$$
\mathrm{SbCl}_{5}(\mathrm{~g}) \rightleftharpoons \mathrm{SbCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})
$$

A sample of 0.50 mol of $\mathrm{SbCl}_{5}$ is placed in a 1.0 L flask and heated to $450{ }^{\circ} \mathrm{C}$. When the system reaches equilibrium there is 0.10 mol of $\mathrm{Cl}_{2}$ present. Calculate the value of the equilibrium constant, $K_{\mathrm{c}}$, at $450^{\circ} \mathrm{C}$.

One mole of $\mathbf{C l}_{\mathbf{2}}$ is generated by the decomposition of one mole of $\mathbf{S b C l}_{5}$. As $\mathbf{0 . 1 0}$ mol of $\mathrm{Cl}_{2}$ is present at equilibrium, $(0.50-0.10)=0.40 \mathrm{~mol}$ of $\mathrm{SbCl}_{5}$ must be left.

One mole of $\mathrm{SbCl}_{3}$ is generated alongside the production of one mole of $\mathrm{Cl}_{2}$ so the number of moles of $\mathbf{S b C l}_{3}=$ number of moles of $\mathbf{C l}_{2}=\mathbf{0 . 1 0} \mathbf{~ m o l}$.

The volume of the flask is 1.0 L so the concentration $=\frac{\text { number of moles }}{\text { volume }}$. The concentrations are therefore: $\left[\mathbf{S b C l}_{\mathbf{5}}(\mathrm{g})\right]=\mathbf{0 . 4 0} \mathbf{M},\left[\mathrm{Cl}_{\mathbf{2}}(\mathrm{g})\right]=\left[\mathrm{SbCl}_{3}(\mathrm{~g})\right]=\mathbf{0 . 1 0} \mathbf{M}$.

The equilibrium constant in terms of concentrations, $\mathbf{K}_{\boldsymbol{c}}$, is therefore:

$$
K_{c}=\frac{\left[\mathrm{Cl}_{2}(\mathrm{~g})\right]\left[\left[\mathrm{SbCl}_{3}(\mathrm{~g})\right]\right.}{\left[\mathrm{SbCl}_{5}(\mathrm{~g})\right]}=\frac{(0.10) \times(0.10)}{(0.40)}=0.025
$$

Answer: $\mathbf{K}_{\mathbf{c}}=\mathbf{0 . 0 2 5}$

- Consider a cell composed of the following half-reactions.

$$
\begin{aligned}
& \mathrm{Ce}^{4+}(\mathrm{aq})+\mathrm{e}^{-} \rightarrow \mathrm{Ce}^{3+}(\mathrm{aq}) \\
& \mathrm{Cr}(\mathrm{~s}) \rightarrow \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{e}^{-}
\end{aligned}
$$

What is the balanced equation for the spontaneous reaction?

$$
3 \mathrm{Ce}^{4+}(\mathrm{aq})+\mathrm{Cr}(\mathrm{~s}) \rightarrow 3 \mathrm{Ce}^{3+}(\mathrm{aq})+\mathrm{Cr}^{3+}(\mathrm{aq})
$$

What is the value of $E^{\circ}$ for the cell? Relevant standard reduction potentials are on the data sheet.

The electrode potentials are:

$$
\begin{array}{ll}
\mathrm{Ce}^{4+}(\mathrm{aq})+\mathrm{e}^{-} \rightarrow \mathrm{Ce}^{3+}(\mathrm{aq}) & \mathrm{E}^{\circ}=+\mathbf{1 . 7 2} \mathrm{V} \\
\mathrm{Cr}(\mathrm{~s}) \rightarrow \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{e}^{-} & \mathrm{E}^{\circ}=+\mathbf{0 . 7 4} \mathrm{V} \text { (reversed as oxidation required) }
\end{array}
$$

The standard cell potential is therefore: $\mathrm{E}^{\circ}=(+1.72)+(+0.74)=+2.46 \mathrm{~V}$

> Answer: +2.46 V

- What does the superscript " o " mean in the symbol $\Delta H_{\mathrm{f}}{ }^{\circ}$ ?

The enthalpy change corresponds to all reactants and products being in their standard states (gases at pressures of 100 kPa , solutions of 1 M concentration and elements in their common form at 100 kPa and 273 K )

- Calculate the standard heat of reaction for the following reaction.

$$
\mathrm{Zn}(\mathrm{~s})+\mathrm{Cu}^{2+}(\mathrm{aq}) \rightarrow \mathrm{Cu}(\mathrm{~s})+\mathrm{Zn}^{2+}(\mathrm{aq})
$$

Data: $\quad \Delta H_{\mathrm{f}}^{\mathrm{o}}=+64.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for $\mathrm{Cu}^{2+}(\mathrm{aq})$

$$
\Delta H_{\mathrm{f}}^{\mathrm{o}}=-152.4 \mathrm{~kJ} \mathrm{~mol}^{-1} \text { for } \mathrm{Zn}^{2+}(\mathrm{aq})
$$

The enthalpy of the reaction is given by:

$$
\begin{aligned}
\Delta_{\mathbf{r x n}} \mathbf{H}^{\mathbf{0}} & =\sum \mathrm{m} \Delta_{\mathrm{f}} \mathbf{H}^{\mathbf{0}}(\text { products })-\sum \mathrm{n} \Delta_{\mathrm{f}} \mathbf{H}^{\mathbf{0}}(\text { reactan ts }) \\
& =\left[\Delta_{\mathrm{f}} \mathbf{H}^{\mathbf{0}}\left(\mathrm{Zn}^{2+}(\mathrm{aq})\right)\right]-\left[\Delta_{\mathrm{f}} \mathbf{H}^{\mathbf{0}}\left(\mathbf{C u}^{2+}(\mathrm{aq})\right)\right] \\
& =(-152.4)-(+\mathbf{6 4 . 4})=-\mathbf{2 1 6 . 8} \mathrm{kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

(Note that $\Delta_{f} \mathbf{H}^{\mathbf{0}}(\mathbf{Z n}(\mathrm{s}))$ and $\Delta_{\mathrm{f}} \mathbf{H}^{\mathbf{0}}(\mathbf{C u}(\mathrm{s}))$ are both zero as these elements are in the standard states).

$$
\text { Answer: - } \mathbf{- 2 1 6 . 8} \mathbf{k J ~ m o l}^{-1}
$$

- Write a balanced ionic equation for the reaction of solid sodium hydrogencarbonate, $\mathrm{NaHCO}_{3}$, and dilute sulfuric acid, $\mathrm{H}_{2} \mathrm{SO}_{4}$.

$$
\mathrm{NaHCO}_{3}(\mathrm{~s})+\mathrm{H}^{+}(\mathrm{aq}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathbf{l})+\mathrm{CO}_{2}(\mathrm{~g})
$$

- Calculate the mass of silver nitrate, $\mathrm{AgNO}_{3}$, required to make 500 mL of 0.200 M aqueous solution.

The number of moles of $\mathrm{AgNO}_{3}$ in 500 mL of a 0.200 M solution is:

$$
\text { number of moles }=\text { concentration } \times \text { volume }=0.200 \times \frac{500}{1000}=0.100 \mathrm{~mol}
$$

The formula mass of $\mathrm{AgNO}_{3}$ is:

$$
\text { formula mass }=(107.87(\mathrm{Ag}))+(14.01(\mathrm{~N}))+(3 \times 16.00(\mathrm{O}))=169.88
$$

The mass of $\mathbf{0 . 1 0 0} \mathbf{~ m o l}$ is therefore $\mathbf{0 . 1 0 0} \times \mathbf{1 6 9 . 8 8}=\mathbf{1 7 . 0} \mathrm{g}$

Answer: $\mathbf{1 7 . 0} \mathbf{g}$
Calculate the time required (in minutes) to deposit 7.0 g of silver from a 0.200 M silver nitrate solution using a current of 4.5 A .

The number of moles of silver in 7.0 g is $\frac{\text { mass }}{\text { atomic mass }}=\frac{\mathbf{7 . 0}}{\mathbf{1 0 7 . 8 7}}=\mathbf{0 . 0 6 5} \mathbf{m o l}$ To deposit silver requires reduction of $\mathbf{A g}^{+}(\mathbf{a q})$, requiring 1 mole of electrons per mole of silver. Hence, 0.065 mol of electrons is required. This corresponds to a charge of $\mathrm{Q}=\mathrm{nF}=\mathbf{0 . 0 6 5} \times \mathrm{F}=\mathbf{0 . 0 6 5} \times \mathbf{9 6 4 8 5}=\mathbf{6 3 0 0} \mathrm{C}$.

As $Q=I \times t$, the time taken to deliver this charge at a current of 4.5 A is:

$$
t=\frac{Q}{I}=\frac{6300}{4.5}=1400 \mathrm{~s}=23 \text { minutes }
$$

## Answer: $\mathbf{2 3}$ minutes

- A lead-acid battery has the following shorthand notation:
$\mathrm{Pb}(\mathrm{s}), \mathrm{PbSO}_{4}(\mathrm{~s})\left|\mathrm{H}^{+}(\mathrm{aq}), \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \| \mathrm{H}^{+}(\mathrm{aq}), \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})\right| \mathrm{PbO}_{2}(\mathrm{~s}), \mathrm{PbSO}_{4}(\mathrm{~s})$

Which component of the battery is the anode?
$\mathbf{P b}(\mathbf{s}), \mathrm{PbSO}_{4}(\mathbf{s})$

Give the balanced half equation of the reaction that takes place at the anode.

$$
\mathbf{P b}(\mathbf{s})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \rightarrow \mathrm{PbSO}_{4}(\mathrm{~s})+2 \mathrm{e}^{-}
$$

Which component of the battery is the cathode?
$\mathrm{PbO}_{2}(\mathbf{s}), \mathrm{PbSO}_{4}(\mathbf{s})$

Give the balanced half equation of the reaction that takes place at the cathode.

$$
\mathbf{P b O}_{2}(\mathrm{~s})+4 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+2 \mathrm{e}^{-} \rightarrow \mathrm{PbSO}_{4}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathbf{l})
$$

- When "dry ice", solid carbon dioxide, is heated to 400 K it becomes gaseous. An 88.0 g sample of solid carbon dioxide is placed into a sealed 100 L container that is initially at a pressure of 1.00 atm and a temperature of 298 K . The container is heated to 400 K . What will be the final pressure inside the container?

The molar mass of $\mathrm{CO}_{2}$ is $(12.01(\mathrm{C}))+(2 \times 16.00(\mathrm{O}))=44.01$. The sample of 88.0 g therefore corresponds to:

$$
\text { moles of } \mathrm{CO}_{2}=\frac{\text { mass }}{\text { molar mass }}=\frac{88.0}{44.01}=2.00 \mathrm{~mol}
$$

The pressure due to this amount of $\mathrm{CO}_{2}$ in a container of volume 100 L at 400 K is given by the ideal gas law, $\mathrm{PV}=\mathrm{nRT}$, as:

$$
p_{\mathrm{CO}_{2}}=\frac{\mathrm{nRT}}{\mathrm{~V}}=\frac{(2.00) \times(0.08206) \times(400)}{100}=0.656 \mathrm{~atm}
$$

The container initially contained a gas with a pressure of 1.00 atm at 298 K . The ideal gas equation can be applied to this gas at the two temperatures and as the number of moles and the volume is constant, this gas will have a pressure at 400 $K$ corresponding to:

$$
\frac{p\left(T_{2}\right)}{p\left(T_{1}\right)}=\frac{T_{2}}{T_{1}} \text { or } p(400 \mathrm{~K})=p(298 \mathrm{~K}) \times \frac{400}{298}=1.00 \times \frac{400}{298}=1.34 \mathrm{~atm}
$$

The total pressure at 400 K is therefore $0.656+1.34=2.00 \mathrm{~atm}$

Answer: 2.00 atm
