- Complete the following table, including resonance structures where appropriate. The central atom is underlined.

| Species | Lewis structure | Molecular geometry | Is the species polar? |
| :---: | :---: | :---: | :---: |
| $\mathrm{NF}_{3}$ |  |  <br> Trigonal pyramidal | Yes |
| $\underline{S O}_{2}$ | $\ddot{O}=\stackrel{O}{0}=0$ |  | Yes |
| $\mathrm{ClF}_{5}$ |  |  <br> Square-based pyramidal | Yes |
| $\mathrm{BH}_{3}$ |  |  <br> Trigonal planar | No |

THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY

- Explain the term 'resonance structures' and give an example.

Resonance structures are different valid Lewis structures for a molecule or ion. The true distribution of electrons is an average of all of the different resonance structures.

For example, there are three equivalent resonance structures for the $\mathrm{NO}_{3}{ }^{-}$ion:

- Explain why stable compounds of oxygen have 8 electrons in the valence shell, but compounds of sulfur may have 8,10 or 12 electrons in their valence shell.

Oxygen belongs to the $2^{\text {nd }}$ period and there is only space for 8 electrons in its valence shell. Stable compounds of oxygen obey the octet rule.
Sulfur belongs to the $3^{\text {rd }}$ period and there is space for up to $\mathbf{1 8}$ electrons in its valence shell. It has 6 valence electrons and can use 2,4 or 6 of these to make covalent bonds leading to molecules like $\mathrm{SF}_{2}, \mathrm{SF}_{4}$ and $\mathrm{SF}_{6}$ respectively. These have 8, 10 and 12 electrons around sulfur respectively.

- In the spaces provided, briefly explain the meaning of the following terms.

## Valence electrons

The electrons in the outer shell of an atom that can contribute to bonding.

## Polar bond

A covalent bond involving two elements of different electronegativity. The different electronegativities lead to an unequal share of the bonding electrons, resulting in a partial positive charge at one end and a partial negative charge at the other end of the bond.

Intensive properties
A physical property of a substance such as density that does not depend on the amount of the substance present.

- In an experiment, 5.0 g of magnesium was dissolved in excess hydrochloric acid to give magnesium ions and hydrogen gas. Write a balanced equation for the reaction that occurred.

$$
\mathbf{M g}(\mathrm{s})+\mathbf{2 \mathbf { H } ^ { + } ( \mathrm { aq } )} \rightarrow \mathbf{M g}^{2+}(\mathrm{aq})+\mathbf{H}_{2}(\mathrm{~g})
$$

What amount of hydrogen gas (in mol ) is produced in the reaction?
The molar mass of $\mathbf{M g}$ is $24.31 \mathrm{~g} \mathrm{~mol}^{-1} .5 .0 \mathrm{~g}$ therefore corresponds to:

$$
\text { number of moles }=\text { mass } / \text { molar mass }=5.0 \mathrm{~g} / 24.31 \mathrm{~g} \mathrm{~mol}^{-1}=0.21 \mathrm{~mol}
$$

From the chemical equation, each mol of $\mathbf{M g}$ that reacts will give one mol of $\mathrm{H}_{\mathbf{2}}$. Hence,
number of moles of $\mathbf{H}_{\mathbf{2}}=\mathbf{0 . 2 1} \mathbf{~ m o l}$.

Answer: $\mathbf{0 . 2 1} \mathbf{~ m o l}$
What volume would the hydrogen occupy at $25^{\circ} \mathrm{C}$ and 100.0 kPa pressure?

Using the ideal gas law, $P V=n R T$. Hence,

$$
\begin{aligned}
V & =n R T / P \\
& =(0.21 \mathrm{~mol}) \times\left(8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}\right) \times((25+273) \mathrm{K}) /\left(100.0 \times 10^{3} \mathrm{~Pa}\right) \\
& =0.0051 \mathrm{~m}^{3}
\end{aligned}
$$

As $1 \mathbf{m}^{3}=1000 \mathrm{~L}$, this corresponds to:

$$
V=1000 \times 0.0051 \mathrm{~L}=5.1 \mathrm{~L}
$$

## Answer: 5.1 L

- Silicon and carbon are both in Group 14 and form dioxides. Carbon dioxide is a gas at room temperature while silicon dioxide (sand) is a solid with a high melting point. Describe the bonding in these two materials and explain the differences in properties they show.
$\mathrm{CO}_{2}$ contains discrete molecules. Carbon makes four bonds by making two $\mathbf{C = O}$ double bonds. The $\mathbf{C}=\mathbf{O}$ double bonds have strong $\sigma$ and $\pi$ components. Although these bonds are quite polar, these molecules are linear and do not possess dipole moments. Only very weak dispersion intermolecular forces hold the molecules together and $\mathrm{CO}_{2}$ is a gas at room temperature.
$\mathrm{SiO}_{2}$ is a network covalent solid. Each silicon makes four bonds by making four Si-O single bonds. The covalent network leads to a very strongly bonded solid with a very high melting point.
- Complete the following table by filling in the compound name or formula as required.
- In the Periodic Table given, hydrogen is placed at the top of Group 1. List reasons for and against placing hydrogen in this position.
For:
- It has one valence electron, just like the other members of Group 1
- This electron is in a s-orbital, just like the other members of Group 1
- It has a valency of 1 , just like the other members of Group 1
- It has low electronegativity, just like the other members of Group 1

## Against:

- Unlike the other members of Group 1 , it is a non-metal
- Unlike the other members of Group 1, it exists as diatomic molecules
- Unlike the other members of Group 1, it can form both a cation $\left(\mathbf{H}^{+}\right)$and an anion ( $\mathrm{H}^{-}$)
- Unlike the other members of Group 1, it is 1 electron short of a noble gas configuration
- It forms covalent molecules with non-metals rather than ionic compounds
- It is much more electronegative than the other members of Group 1

THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- A 0.060 M solution of aluminium nitrate and a 0.080 M solution of potassium phosphate are prepared by dissolving $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ and $\mathrm{K}_{3} \mathrm{PO}_{4}$ in water. Write the ionic equations for these two dissolutions reactions.

Dissolution of $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$

Dissolution of $\mathrm{K}_{3} \mathrm{PO}_{4}$

$$
\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}(\mathrm{~s}) \rightarrow \mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{NO}_{3}^{-}(\mathrm{aq})
$$

$\mathrm{K}_{3} \mathrm{PO}_{4}(\mathrm{~s}) \rightarrow \mathbf{3} \mathrm{K}^{+}(\mathrm{aq})+\mathbf{P O}_{4}{ }^{3-}(\mathrm{aq})$
If these solutions are combined, aluminium phosphate precipitates. Write the ionic equation for the precipitation reaction.

$$
\mathrm{Al}^{3+}(\mathrm{aq})+\mathrm{PO}_{4}{ }^{3-}(\mathrm{aq}) \rightarrow \mathrm{AlPO}_{4}(\mathrm{~s})
$$

100.0 mL of the aluminium nitrate solution is added to 50.0 mL of the potassium phosphate solution. What amount (in mol) of aluminium phosphate precipitates?
100.0 mL of a 0.060 M solution of $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ contains:

$$
\begin{aligned}
\text { number of moles of } \mathrm{Al}^{3+} & =\text { concentration } \times \text { volume }=c \times V \\
& =0.060 \mathrm{~mol}_{\mathrm{L}^{-1} \times 0.1000 \mathrm{~L}}=0.0060 \mathrm{~mol}
\end{aligned}
$$

50.0 mL of a 0.080 M solution of $\mathrm{K}_{\mathbf{3}} \mathrm{PO}_{\mathbf{4}}$ contains:

$$
\text { number of moles of } \begin{aligned}
\mathrm{PO}_{4}{ }^{3-} & =\text { concentration } \times \text { volume }=c \times V \\
& =0.080 \mathrm{~mol} \mathrm{~L}^{-1} \times 0.0500 \mathrm{~L}=0.0040 \mathrm{~mol}
\end{aligned}
$$

As the ionic equation has a $1: 1$ ratio of $\mathrm{Al}^{3+}$ : $\mathrm{PO}_{4}{ }^{3-}$ reacting, $\mathrm{PO}_{4}{ }^{3-}$ is the limiting reagent. The ionic equation shows that 1 mol of $\mathrm{AlPO}_{4}$ is made from 1 mol of $\mathrm{PO}_{4}{ }^{3-}$ so 0.0040 mol will produce 0.0040 mol .

Answer: $\mathbf{0 . 0 0 4 0 ~ m o l}$
What is the final concentration of aluminium ions remaining in solution after the precipitation?

Formation of 0.0040 mol of $\mathrm{AlPO}_{4}$ requires $0.0040 \mathrm{~mol} \mathrm{of} \mathrm{Al}^{3+}$. Therefore, the amount remaining is:

$$
\text { number of moles of } \mathrm{Al}^{3^{+}+} \text {remaining }=(0.0060-0.0040) \mathrm{mol}=0.0020 \mathrm{~mol}
$$

After mixing the total solution volume is $(\mathbf{1 0 0 . 0}+\mathbf{5 0 . 0}) \mathbf{m L}=\mathbf{1 5 0 . 0} \mathbf{~ m L}$. Hence, the concentration of $\mathrm{Al}^{3+}(\mathrm{aq})$ is:

$$
\begin{aligned}
\text { concentration } & =\text { number of moles } / \text { volume }=n / V \\
& =0.0020 \mathrm{~mol} / 0.1500 \mathrm{~L}=0.013 \mathrm{~mol} \mathrm{~L}
\end{aligned}
$$

Answer: $\mathbf{0 . 0 1 3} \mathbf{~ M}$

- By adding double bonds and lone pairs, complete the structural formulae of the nitrogen bases adenine and thymine below.

In DNA, these two molecules interact through two hydrogen bonds. Redraw the structures below showing the alignment of the two molecules that allows this to occur and clearly show the hydrogen bonds.

- Rechargeable nickel-cadmium batteries normally operate (discharge) with the following oxidation and reduction half-cell reactions.

$$
\begin{array}{ll}
\mathrm{Cd}(\mathrm{~s})+2 \mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{Cd}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{e}^{-} & E^{\circ}=0.82 \mathrm{~V} \\
\mathrm{NiO}(\mathrm{OH})(\mathrm{s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{e}^{-} \rightarrow \mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{OH}^{-}(\mathrm{aq}) & E^{\circ}=0.60 \mathrm{~V}
\end{array}
$$

Write out a balanced overall cell reaction.

$$
\mathrm{Cd}(\mathrm{~s})+2 \mathrm{NiO}(\mathrm{OH})(\mathrm{s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Cd}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})
$$

Calculate the overall cell potential.

$$
E_{\text {cell }}^{\circ}=E_{\text {oxidation }}^{\circ}+E_{\text {reduction }}^{\circ}=(0.82+0.60) \mathrm{V}=+1.42 \mathrm{~V}
$$

Answer: + $\mathbf{1 . 4 2}$ V
Using your balanced cell reaction, briefly explain why the cell potential does not change as the battery discharges itself.

Cell potentials depend on concentrations (as quantified using the Nernst equation). The overall cell reaction only involves solids and a pure liquid. The concentration of solids and pure liquids are constant during the reaction (until they are used up). As the concentrations do not change, the cell potential remains constant (until the battery is used up.)

Write out the balanced overall reaction that occurs when this battery is being recharged.
$\mathrm{Cd}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{Ni}(\mathbf{O H})_{2}(\mathrm{~s}) \rightarrow \mathbf{C d}(\mathrm{s})+\mathbf{2 N i O}(\mathbf{O H})(\mathrm{s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$

A current of 2.75 A is measured during recharging with an external potential of 2.0 V . After 5.00 minutes charging, how many moles of $\mathrm{Cd}(\mathrm{s})$ will be redeposited?

The number of moles of electrons used is given by:

$$
\begin{aligned}
\text { number of moles of } \mathrm{e}^{-} & =I t / F \\
& =(\mathbf{2 . 7 5} \mathrm{A}) \times(5.00 \times 60.00 \mathrm{~s}) /\left(96485 \mathrm{C} \mathrm{~mol}^{-1}\right) \\
& =\mathbf{0 . 0 0 8 5 5} \mathrm{mol}
\end{aligned}
$$

From the half-cell reaction, each mole of $\mathrm{Cd}(\mathrm{s})$ requires 2 mol of electrons. The number of moles of $\mathrm{Cd}(\mathrm{s})$ redeposited is therefore:

```
number of moles of Cd(s)=1/2 }\times\mathbf{0.00855 mol = 0.00428 mol
```

- A certain mixture of gases containing 0.24 mol of $\mathrm{He}, 0.53 \mathrm{~mol}$ of $\mathrm{N}_{2}$ and 0.05 mol of Ne is placed in a container with a piston that maintains it at a total pressure of 1.0 atm . This gas mixture is now heated from its initial temperature of 290 K to 370 K by passing 2.08 kJ of energy into it.
Calculate the volume occupied by the gas at 370 K .

The total number of moles of gas $=(0.24+0.53+0.05) \mathbf{m o l}=\mathbf{0 . 8 2} \mathbf{~ m o l}$.
Using the ideal gas law, $P V=n R T$, the volume occupied is:

$$
\begin{aligned}
V & =n R T / P \\
& =(0.82 \mathbf{~ m o l}) \times\left(0.08206 \mathrm{~L} \mathrm{~atm} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}\right) \times(370 \mathrm{~K}) /(1.0 \mathrm{~atm}) \\
& =25 \mathrm{~L}
\end{aligned}
$$

Answer: $\mathbf{2 5}$ L
Calculate the heat capacity of the gas mixture (in $\mathrm{J} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ ).

The temperature change $=\Delta T=(370-290)=80 \mathrm{~K}$. This is produced using a heat change of 2.08 kJ .

Using $q=n C \Delta T$, the molar heat capacity is:

$$
C=q / n \Delta T=\left(2.08 \times 10^{3} \mathrm{~J}\right) /(0.82 \mathrm{~mol} \times 80 \mathrm{~K})=30 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}
$$

Answer: $\mathbf{3 0} \mathbf{~ J ~ K}^{-1} \mathbf{~ m o l}^{-1}$
THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- Nitrogen and acetylene gases react to form hydrogen cyanide according to the reaction

$$
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HCN}(\mathrm{~g}) \quad K_{\mathrm{c}}=2.3 \times 10^{-4} \text { at } 300^{\circ} \mathrm{C}
$$

Write out the equilibrium constant expression for $K_{\mathrm{c}}$ for this reaction as shown above.

$$
K_{\mathrm{c}}=\frac{[\mathrm{HCN}(\mathrm{~g})]^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})\right]}
$$

The value of $K_{\mathrm{p}}$ for this reaction at $300^{\circ} \mathrm{C}$ is also $2.3 \times 10^{-4}$. Why are the values of $K_{\mathrm{p}}$ and $K_{\mathrm{c}}$ the same for this reaction?

The number of moles of gas remains constant during the reaction. 2 mol of gas react to give $2 \mathbf{~ m o l}$ of product gas.

Write a balanced equation and calculate the value of the equilibrium constant $K_{\mathrm{c}}^{\prime}$ for the formation of 1.0 mol of hydrogen cyanide gas from nitrogen and acetylene gases.
$1 / 2 \mathrm{~N}_{2}(\mathrm{~g})+1 / 2 \mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{HCN}(\mathrm{g})$
For this reaction, $K_{c}^{\prime}=\frac{[\mathrm{HCN}(\mathrm{g})]}{\left[\mathrm{N}_{2}(\mathrm{~g})\right]^{1 / 2}\left[\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})\right]^{1 / 2}}$

$$
=K_{\mathrm{c}}^{1 / 2}=0.015
$$

Answer: $\mathbf{0 . 0 1 5}$
What is the equilibrium concentration of $\mathrm{HCN}(\mathrm{g})$ if nitrogen and acetylene are mixed so that both are at starting concentrations of $1.0 \mathrm{~mol} \mathrm{~L}^{-1}$ ?

The reaction table for this is:

|  | $1 / 2 \mathrm{~N}_{2}(\mathrm{~g})$ | $1 / 2 \mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})$ | $\rightleftharpoons$ | $\mathrm{HCN}(\mathrm{g})$ |
| :---: | :---: | :---: | :---: | :---: |
| initial | 1.0 | 1.0 |  | 0 |
| change | $-x$ | $-x$ |  | $+2 x$ |
| equilibrium | $1.0-x$ | $1.0-x$ |  | $2 x$ |

Hence, the equilibrium constant expression in terms of $x$ is:

$$
K_{\mathrm{c}}=\frac{[\mathrm{HCN}(\mathrm{~g})]}{\left[\mathrm{N}_{2}(\mathrm{~g})\right]^{1 / 2}\left[\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})\right]^{1 / 2}}=\frac{(2 x)}{(1.0-x)^{1 / 2}(1.0-x)^{1 / 2}}=\frac{2 x}{(1.0-x)}=0.015
$$

So,

$$
\begin{aligned}
& 2 x=0.015-0.015 x \\
& 2.015 x=0.015 \\
& x=0.0074
\end{aligned}
$$

## Hence,

$[\mathrm{HCN}(\mathrm{g})=2 x \mathrm{~N}=0.015 \mathrm{M}$
(The 'small $x$ ' approximation can be used but as no quadratic needs to be solved, this is unnecessary.)

- The boiling point of $\mathrm{NH}_{3}$ is $-33^{\circ} \mathrm{C}$ and that of HF is $+20^{\circ} \mathrm{C}$. Explain this difference in terms of the strengths of the intermolecular forces between these molecules.

The strongest intermolecular force in both comes from hydrogen bonding.
Each HF molecule possesses 3 lone pairs on F and 1 H . HF molecules on average make 2 H-bonds.

Each $\mathbf{N H}_{3}$ molecule possesses 1 lone pair on $\mathbf{N}$ and $\mathbf{3} \mathbf{H}$. $\mathbf{N H}_{3}$ molecules on average also make 2 H -bonds.

As fluorine is more electronegative than nitrogen, the H-F bonds are much more polar than the N-H bonds. Due to the higher partial charges on $H$ and $F$ in HF, a hydrogen bond between $\mathbf{H F}$ molecules is stronger than that between $\mathbf{N H}_{3}$ molecules.

The higher boiling point of HF is thus due to stronger H-bonds.

Explain why the boiling point of water $\left(100^{\circ} \mathrm{C}\right)$ is higher than both HF and $\mathrm{NH}_{3}$.

The polarity of the $\mathrm{O}-\mathrm{H}$ bonds in $\mathrm{H}_{2} \mathrm{O}$ is intermediate between that of $\mathrm{H}-\mathrm{F}$ and N $H$ bonds. It is expected that the individual H -bonds between $\mathrm{H}_{2} \mathrm{O}$ molecules will also be intermediate in strength.

Each $\mathrm{H}_{2} \mathrm{O}$ molecule possesses 2 lone pairs on O and $2 \mathrm{H} . \mathrm{H}_{2} \mathrm{O}$ molecules are thus able to form an average of $4 \mathbf{H}$-bonds.
$\mathrm{H}_{2} \mathrm{O}$ has a higher boiling point than $\mathrm{NH}_{3}$ because (i) the $\mathbf{H}$-bonds are stronger and (ii) it contains twice as many H -bonds.
$\mathrm{H}_{2} \mathrm{O}$ has a higher boiling point than HF because it contains twice as many H bonds, despite these being individually weaker.

THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- Write the equation whose enthalpy change represents the standard enthalpy of formation of $\mathrm{NO}(\mathrm{g})$.
$1 / 2 \mathrm{~N}_{2}(\mathrm{~g})+1 / 2 \mathrm{O}_{\mathbf{2}}(\mathrm{g}) \rightarrow \mathrm{NO}(\mathrm{g})$

Given the following data, calculate the standard enthalpy of formation of $\mathrm{NO}(\mathrm{g})$.

$$
\begin{array}{lll}
\mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) & \rightleftharpoons & \rightleftharpoons \mathrm{NO}_{2}(\mathrm{~g})
\end{array} \begin{aligned}
& \Delta H^{\circ}=66.6 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \\
& \rightleftharpoons
\end{aligned} 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad \Delta H^{\circ}=-114.1 \mathrm{~kJ} \mathrm{~mol}^{-1} .
$$

Using $\Delta_{\mathrm{rxn}} H^{\circ}=\Sigma m \Delta_{\mathrm{f}} H^{\circ}$ (products) $-\Sigma n \Delta_{\mathrm{f}} H^{\circ}$ (reactants), the enthalpy of these two reactions are:
(1) $\Delta H^{\circ}=\left[2 \Delta_{f} H^{\circ}\left(\mathrm{NO}_{2}(\mathrm{~g})\right)\right]=66.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$
(2) $\Delta H^{\circ}=\left[2 \Delta_{f} H^{\circ}\left(\mathrm{NO}_{2}(\mathrm{~g})\right)\right]-\left[2 \Delta_{\mathrm{f}} H^{\circ}(\mathrm{NO}(\mathrm{g}))\right]=-114.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$
where $\Delta_{f} H^{\circ}\left(\mathrm{N}_{2}(\mathrm{~g})\right)=\Delta_{\mathrm{f}} H^{\circ}\left(\mathrm{O}_{2}(\mathrm{~g})\right)=0$ has been used for elements already in their standard states.

Substituting (1) into (2) gives:
$\left(66.6 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)-\left[2 \Delta_{\mathrm{f}} H^{\circ}(\mathrm{NO}(\mathrm{g}))\right]=-114.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$

$$
\left.\Delta_{\mathrm{f}} H^{\circ}(\mathrm{NO}(\mathrm{~g}))\right]=90.4 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

$$
\text { Answer: } \mathbf{+ 9 0 . 4} \mathbf{k J ~ m o l}^{-1}
$$

- Hydrazine, $\mathrm{N}_{2} \mathrm{H}_{4}$, burns completely in oxygen to form $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. Use the bond enthalpies given below to estimate the enthalpy change for this process.

| Bond | Bond enthalpy $\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$ | Bond | Bond enthalpy $\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{N}-\mathrm{H}$ | 391 | $\mathrm{O}=\mathrm{O}$ | 498 |
| $\mathrm{~N}-\mathrm{N}$ | 158 | $\mathrm{O}-\mathrm{O}$ | 144 |
| $\mathrm{~N}=\mathrm{N}$ | 470 | $\mathrm{O}-\mathrm{H}$ | 463 |
| $\mathrm{~N} \equiv \mathrm{~N}$ | 945 | $\mathrm{~N}-\mathrm{O}$ | 214 |

The chemical equation for the combustion is:

$$
\mathrm{N}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

This requires:

- breaking $1 \mathrm{~N}-\mathrm{N}$ bond, 4 N - H bonds and $1 \mathrm{O}=\mathrm{O}$ bond
- making $1 \mathrm{~N} \equiv \mathrm{~N}$ bond and $4 \mathrm{O}-\mathrm{H}$ bonds

Breaking bonds is endothermic:
$\Delta_{\text {breaking }} H^{\circ}=(158+4 \times 391+498) \mathrm{kJ} \mathrm{mol}^{-1}=+2220 \mathrm{~kJ} \mathrm{~mol}^{-1}$
Making bonds is exothermic:
$\Delta_{\text {making }} H^{\circ}=-(945+4 \times 463) \mathrm{kJ} \mathrm{mol}^{-1}=-2797 \mathrm{~kJ} \mathrm{~mol}^{-1}$
Overall,

$$
\Delta H^{\circ}=\Delta_{\text {breaking }} H^{\circ}+\Delta_{\text {making }} H^{\circ}=(2220-2797) \mathrm{kJ} \mathrm{~mol}^{-1}=-577 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$
