- Balance the following nuclear reactions by identifying the missing nuclear particle or nuclide.

| ${ }_{26}^{55} \mathrm{Fe}+{ }_{-1}^{0} \mathrm{e} \rightarrow$ |
| ---: |
| ${ }_{2}^{35} \mathrm{Me}+{ }_{2}^{55} \mathrm{He} \rightarrow 2{ }_{1}^{1} \mathrm{p}+{ }_{{ }_{2}^{4}}^{4} \mathrm{He}$ |
| ${ }_{7}^{15} \mathrm{~N}+{ }_{1}^{1} \mathrm{p} \rightarrow{ }_{8}^{15} \mathrm{O}+{ }_{0}^{1} \mathrm{n}$ |

- Calculate the atomic mass of lead from the isotope information provided.

The relative atomic mass of lead is the weighted average of the masses of its isotopes:

$$
\begin{aligned}
\text { atomic mass }= & \left(203.97304 \times \frac{1.40}{100}\right)+\left(205.97446 \times \frac{24.10}{100}\right)+ \\
& \left(206.97589 \times \frac{22.10}{100}\right)+\left(207.97664 \times \frac{52.40}{100}\right)=207.2
\end{aligned}
$$

(The relative abundances are given to 4 significant figures and limit the accuracy of the answer.)

Answer: 207.2

- Calculate the molar activity of ${ }^{11} \mathrm{C}$ (in curie), given its half-life of 20.3 minutes.

The molar activity is given by $\mathbf{A m o l}_{\mathrm{mol}}=\lambda \mathbf{N}_{\mathbf{a}}$ where $\lambda$ is the decay constant which is related to the half life $t_{1 / 2}$ by $\lambda=\frac{\ln 2}{t_{1 / 2}}$.
The half life $=\mathbf{2 0 . 3}$ minutes or $20.3 \times \mathbf{6 0} \mathrm{s}=\mathbf{1 2 1 8}$ s. Hence the molar activity is:

$$
A_{\text {mol }}=\left(\frac{\ln 2}{1218}\right) \times\left(6.022 \times 10^{23}\right)=3.427 \times 10^{20} \mathrm{~Bq}=\frac{3.427 \times 10^{20}}{3.70 \times 10^{10}} \mathrm{Ci}=9.26 \times 10^{9} \mathrm{Ci}
$$

Answer: $\mathbf{9 . 2 6 \times 1 0} \mathbf{~}{ }^{\mathbf{9}} \mathbf{C i}$

- Provide a brief explanation of each of the following terms. (You may include an equation or a diagram where appropriate).
(a) Pauli exclusion principle

No two electrons may occupy the same orbital with the same spin, thereby having the same set of quantum numbers, $n, l, m_{l}, s$ and $m_{s}$.
(b) the Bohr model of the atom

In the Bohr model, electrons in atoms occupy only discrete circular orbits. By being restricted to certain orbits, the energy of the electron can only have certain discrete values. The orbit occupied is labelled by a quantum number, $n$, which can only take integer values: $n=1,2,3 \ldots$

- Write down the ground state electron configurations for the following elements. The configuration of lithium is given as an example.

| Li | $1 s^{2} 2 s^{1}$ |
| :---: | :--- |
| Ne | $\mathbf{1} s^{2} \mathbf{2} s^{\mathbf{2}} \mathbf{2} p^{6}$ or $[\mathrm{He}] \mathbf{2} p^{6}$ |
| Br | $\mathbf{1} s^{\mathbf{2}} \mathbf{2} s^{\mathbf{2}} \mathbf{2} p^{6} \mathbf{3} s^{\mathbf{2}} \mathbf{3} \boldsymbol{p}^{6} \mathbf{4} s^{\mathbf{2}} \mathbf{3} d^{\mathbf{1 0}} \mathbf{4} p^{5}$ or $[\mathrm{Ar}] \mathbf{4} s^{\mathbf{2}} \mathbf{3} d^{\mathbf{1 0}} \mathbf{4} p^{\mathbf{5}}$ |

- Sketch the following wave functions as lobe representations. Clearly mark all nodal surfaces and nuclear positions.
(a) a $2 p$ orbital
- Complete the following table. Water is given as an example.

| Name | Lewis structure | ```Number of valence electron pairs on central atom``` | Geometric arrangement of valence electron pairs on central atom | Molecular shape |
| :---: | :---: | :---: | :---: | :---: |
| water | $\mathrm{H}-\stackrel{\mathrm{O}}{-}-\mathrm{H}$ | 4 | tetrahedral | bent |
| sulfur hexafluoride |  | 6 | octahedral | octahedral |
| iodine trichloride |  | 5 | trigonal bipyramidal | T-shaped |
| xenon <br> tetrafluoride |  | 6 | octahedral | square <br> planar |

- A typical surface (skin) temperature of an adult human is $33.0^{\circ} \mathrm{C}$. Calculate the wavelength at which the most intense electromagnetic radiation is emitted from the human body.

The wavelength, $\lambda$, is related to the absolute temperature, $T$, through the equation, $4.5 k_{B} T=\frac{h c}{\lambda}$ or:

$$
\lambda=\frac{\mathrm{hc}}{4.5 \mathrm{k}_{\mathrm{B}} \mathrm{~T}}
$$

With $T=33.0+273.0=306 K$,

$$
\lambda=\frac{\left(6.626 \times 10^{-34}\right)\left(2.998 \times 10^{8}\right)}{(4.5)\left(1.381 \times 10^{-23}\right)(306)}=1.04 \times 10^{-6} \mathrm{~m}
$$

(As the temperature is given to 3 significant figures, this limits the accuracy of the answer to the same number of significant figures.)

Answer: $\mathbf{1 . 0 4} \times \mathbf{1 0}^{-5} \mathbf{~ m}$

Calculate the energy of a single photon of this radiation.
The energy is related to the wavelength through the equation, $E=\frac{\mathbf{h c}}{\lambda}$. Hence:

$$
E=\frac{\left(6.626 \times 10^{-34}\right)\left(2.998 \times 10^{8}\right)}{\left(1.04 \times 10^{-6}\right)}=1.90 \times 10^{-20} \mathrm{~J}
$$

- A cartoon representation of the structure of halite $(\mathrm{NaCl})$ is shown below. The structure arises from the closest possible packing of anions stabilized by cations in the interstices. From a density of $2.16 \mathrm{~g} \mathrm{~cm}^{-3}$, a nearest neighbour distance of 282 pm was calculated.

$$
\mathrm{NaCl}: \quad=\mathrm{Na}^{+}, \quad=\mathrm{Cl}^{-}
$$

| Crystal structure | Madelung <br> constant $(A)$ |
| :--- | :---: |
| ZnS (wurtzite) | 1.641 |
| NaCl | 1.748 |
| CsCl | 1.763 |

What is the molar lattice energy of halite?
The molar lattice energy is given by the equation, $E=-A \frac{e^{2}}{4 \pi \varepsilon_{0} r} N_{a}$ where $A$ is the
Madelung constant and $r$ is the separation of the ions which is equal to the nearest neighbour distance. With $\mathbf{r}=\mathbf{2 8 2} \mathbf{~ p m}=\mathbf{2 8 2} \times \mathbf{1 0}^{\mathbf{- 1 2}} \mathbf{m}$ and $\mathrm{A}=\mathbf{1 . 7 4 8}$ for the NaCl structure from the table:

$$
\begin{aligned}
E & =-(1.748) \times \frac{\left(1.602 \times 10^{-19}\right)^{2}}{\left.(4) \times(3.142) \times * 8.8524 \times 10^{-12}\right) \times\left(282 \times 10^{-12}\right)} \times\left(6.022 \times 10^{23}\right) \\
& =859000 \mathrm{~J} \mathrm{~mol}^{-1}=859 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

Answer: $\mathbf{8 5 9} \mathbf{~ k J ~ m o l}^{-1}$
What would be the Madelung constant of lithium chloride given that it does not adopt the wurtzite structure? Explain your answer.

As the lattice energy is proportional to the Madelung constant, a salt will adopt the structure with the maximum possible Madelung constant. The Madelung constant is related to the number of anions surrounding each cation (and vice versa). Thus, the $\mathrm{ZnS}, \mathrm{NaCl}$ and CsCl structures have 4,6 and 8 anions around each cation respectively. The number of anions is limited by the radius ratio rules: the anions must physically fit around the cation.
$\mathrm{Na}^{+}$is large enough to fit $6 \mathrm{Cl}^{-}$around it but not large enough to fit $\mathbf{8} \mathrm{Cl}^{-}$and thus adopts the NaCl structure. $\mathrm{Li}^{+}$is smaller than $\mathrm{Na}^{+}$so is definitely also too small to fit $8 \mathrm{Cl}^{-}$around it. As the question states that it does not adopt the ZnS (wurtzite) structure, it must therefore adopt the $\mathbf{N a C l}$ structure so has $\mathbf{A}=\mathbf{1 . 7 4 8}$.

- The current "petrochemical economy" is based on the combustion of fossil fuels, of which octane is a typical example.

$$
2 \mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{l})+25 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 16 \mathrm{CO}_{2}(\mathrm{~g})+18 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Calculate the heat of combustion of octane using the supplied heat of formation data.
Data: $\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{l}):-249.9 \mathrm{~kJ} \mathrm{~mol}^{-1} ; \mathrm{CO}_{2}(\mathrm{~g}):-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1} ; \mathrm{H}_{2} \mathrm{O}(\mathrm{l}):-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}$

Using $\Delta_{\mathrm{rxn}} \mathrm{H}^{\mathbf{0}}=\sum \mathrm{m} \Delta_{\mathrm{f}} \mathrm{H}^{\mathbf{0}}$ (products) $-\sum \mathrm{n} \Delta_{\mathrm{f}} H^{\mathbf{0}}$ (reactants), the heat of the reaction as written is:

$$
\begin{aligned}
\Delta_{\mathrm{rxn}} \mathrm{H}^{0} & =\left[16 \Delta_{\mathrm{f}} \mathrm{H}^{0}\left(\mathrm{CO}_{2}(\mathrm{~g})\right)+18 \Delta_{\mathrm{f}} \mathrm{H}^{0}\left(\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right)\right]-\left[2 \Delta_{\mathrm{f}} \mathrm{H}^{0}\left(\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{l})\right)\right] \\
& =[(16 \times-393.5)+(18 \times-285.8)]-[(2 \times-249.9)] \\
& =-10940 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

where $\Delta_{f} \mathbf{H}^{\mathbf{0}}\left(\mathrm{O}_{\mathbf{2}}(\mathrm{g})\right)=\mathbf{0}$ has been used for the formation of an element in its standard state.

The enthalpy of combustion is defined per mole of fuel. The above reaction is for the combustion of two moles of $\mathrm{C}_{8} \mathrm{H}_{18}$.

Hence, $\Delta_{\text {comb }} \mathbf{H}^{0}=1 / 2 \times-10940=-5470 \mathrm{~kJ} \mathrm{~mol}^{-1}$
Answer: - $\mathbf{- 5 4 7 0} \mathbf{~ k J ~ m o l}{ }^{\mathbf{1}}$
How much energy is released when 1.00 L of octane is burned?
Data: Density of octane is $0.67 \mathrm{~kg} \mathrm{~L}^{-1}$

$$
\begin{aligned}
& \text { As density }=\frac{\text { mass }}{\text { volume }}, 1.00 \mathrm{~L} \text { corresponds to: } \\
& \qquad \text { mass }=\text { density } \times \text { volume }=0.67 \times 1.00=0.67 \mathrm{~kg}=670 \mathrm{~g} .
\end{aligned}
$$

The molar mass of octane, $\mathrm{C}_{8} \mathrm{H}_{18}$, is $\mathbf{8} \times \mathbf{1 2 . 0 1}(\mathrm{C})+\mathbf{1 8} \times \mathbf{1 . 0 0 8}(\mathrm{H})=\mathbf{1 1 4 . 2 2 4}$. This mass of octane therefore corresponds to:

$$
\text { number of moles }=\frac{\text { mass }}{\text { molar mass }}=\frac{670}{114.224}=5.9 \mathrm{~mol}
$$

From above, 1 mole releases $5470 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Therefore, this amount release:

$$
\text { energy released }=5.9 \times 5470=32 \times 10^{3} \mathrm{~kJ}=32 \mathrm{MJ}
$$

- The so-called "hydrogen economy" is based on $\mathrm{H}_{2}(\mathrm{~g})$ produced from water by solar energy. The gas is then burned as fuel:

$$
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta H_{\mathrm{r}}=-571.6 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

Calculate the volume of $\mathrm{H}_{2}$ gas at $25^{\circ} \mathrm{C}$ and 1 atm required to produce $1.0 \times 10^{4} \mathrm{~kJ}$ of heat.

From the chemical equation, burning of two moles of $\mathbf{H}_{\mathbf{2}}(\mathrm{g})$ produces 571.6 kJ . so one mole produces $1 / 2 \times 571.6=285.8 \mathrm{~kJ}$ mol.

To produce $1.0 \times 10^{4} \mathrm{~kJ}$ therefore requires:

$$
\text { amount of } \mathrm{H}_{2}(\mathrm{~g}) \text { required }=\frac{1.0 \times 10^{4}}{285.5}=35 \mathrm{~mol}
$$

At $25^{\circ} \mathrm{C}$ and $1 \mathrm{~atm}, 1$ mole of an ideal gas has a volume of 24.5 L . This amount therefore has a volume of:

$$
\text { volume }=35 \times 24.5=860 \mathrm{~L}
$$

Alternatively, and entirely equivalently, the ideal gas law $\mathbf{P V}=\mathbf{n R T}$ can be used:

$$
V=\frac{n R T}{P}=\frac{(35) \times(0.08206) \times(25+273)}{(1)}=860 \mathrm{~L}
$$

A major disadvantage of hydrogen as a fuel is that it is a gas, and therefore hard to store. There is an enormous world-wide effort, including research performed in the University of Sydney, to develop novel chemical structures in which $\mathrm{H}_{2}$ can be stored much more efficiently. One of the structures being tested in the School of Chemistry is shown below.

What type of intermolecular force (or forces) are responsible for the binding between the $\mathrm{Cu}^{2+}$ and the $\mathrm{H}_{2}$ ?

There are ion-induced dipole forces between $\mathrm{Cu}^{2+}$ and the $\mathbf{H}_{\mathbf{2}}$ molecules as well as weak dispersion (London or induced dipole-induced dipole) forces.

In order that such a material be useful for fuel storage, the binding of the $\mathrm{H}_{2}$ must be reversible:

$$
\text { cage }(\mathrm{s})+\mathrm{H}_{2}(\mathrm{~g}) \quad \rightleftharpoons \text { cage } \cdot \mathrm{H}_{2}(\mathrm{~s})
$$

One simple way to reverse the binding is to increase the temperature, so that at low temperature the equilibrium lies to the right and at high temperature to the left. Use this information, plus any chemical knowledge or intuition to infer the sign of $\Delta G$, $\Delta H$ and $\Delta S$ at "low" and "high" temperatures. (You may assume that $\Delta H$ and $\Delta S$ do not change greatly with temperature.)

## At low temperature, the equilibrium lies to the right favouring products:

 $\Delta G<\mathbf{0}$. At high temperature, it lies to the left favouring reactants: $\Delta G>0$.The reaction involves formation of a solid from a solid and a gas. There is therefore a decrease in the entropy: $\Delta S<0$. This is true at all temperatures.

The forward reaction becomes less favourable as the temperature is increased. Le Chatelier's principle therefore suggests that the reaction is exothermic: $\Delta H<0$. This is true at all temperatures. (If the temperature is increased, the equilibrium shifts to remove heat by increasing the backward reaction.)

| Temperature | $\Delta \mathbf{G}$ | $\Delta \mathbf{S}$ | $\boldsymbol{\Delta H}$ |
| :---: | :---: | :---: | :---: |
| low | $<\mathbf{0}$ | $<\mathbf{0}$ | $<\mathbf{0}$ |
| high | $>0$ | $<\mathbf{0}$ | $<\mathbf{0}$ |

- $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{O}_{2}(\mathrm{~g})$ react with each other to a small extent if a catalyst is present to form nitric oxide, $\mathrm{NO}(\mathrm{g})$, according to the following equation.

$$
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}(\mathrm{~g})
$$

The equilibrium constant, $K_{\mathrm{p}}$, for this reaction is $4.35 \times 10^{35}$ at 298 K and $2.75 \times 10^{-20}$ at 500 K . Is the reaction exothermic or endothermic? Give reasons for your answer.

The reaction is favoured at higher temperatures (i.e. increasing the temperature increases the amount of product). Le Chatelier's principle therefore suggests that the reaction is endothermic: $\Delta H>0$

The partial pressures of $\mathrm{O}_{2}(\mathrm{~g})$ and $\mathrm{N}_{2}(\mathrm{~g})$ in air are 0.210 atm and 0.780 atm respectively. If air at atmospheric pressure is sealed in a 1.00 L container containing the catalyst at 298 K , what will be the partial pressure of $\mathrm{NO}(\mathrm{g})$ and the total pressure inside the container at equilibrium?

Two moles of NO are produced for every mole of $\mathrm{O}_{\mathbf{2}}$ and $\mathrm{N}_{\mathbf{2}}$ that is lost.

| partial pressures | $\mathrm{O}_{2}$ | $\mathrm{~N}_{2}$ | NO |
| :---: | :---: | :---: | :---: |
| start | 0.21 | 0.78 | 0 |
| change | -x | -x | +2 x |
| equilibrium | $0.21-\mathrm{x}$ | $0.78-\mathrm{x}$ | $\mathbf{2 x}$ |

The equilibrium constant in terms of partial pressures is then:

$$
K_{\mathrm{p}}=\frac{\left(p_{\mathrm{NO}}\right)^{2}}{\left(p_{\mathrm{O}_{2}}\right)\left(p_{\mathrm{N}_{2}}\right)}=\frac{(2 \mathrm{x})^{2}}{(0.21-\mathrm{x})(0.78-\mathrm{x})}=4.35 \times 10^{-35}
$$

As $K_{\mathrm{p}}$ is very small, x will be tiny so that $(0.21-\mathrm{x}) \sim 0.21$ and $(0.78-\mathrm{x}) \sim 0.78$ to a very good approximation. Substituting these approximations in gives:

$$
4 x^{2}=\left(4.35 \times 10^{-35}\right) \times(0.21) \times(0.78) \Rightarrow x=1.33 \times 10^{-18}
$$

The partial pressure of NO is twice this value $=2.67 \times 10^{-18} \mathrm{~atm}$

The overall number of moles of gas does not change during the reaction so neither does the total pressure. The pressure at equilibrium $=\mathbf{1 . 0 0} \mathbf{~ a t m}$

| Pressure of $\mathrm{NO}(\mathrm{g}): \mathbf{2 . 6 7} \times \mathbf{1 0}^{-18} \mathbf{a t m}$ | Total pressure: $\mathbf{1 . 0 0} \mathbf{~ a t m}$ |
| :--- | :--- |

## THIS QUESTION CONTINUES ON THE NEXT PAGE.

Oxidation of $\mathrm{NO}(\mathrm{g})$ to produce the pollutant $\mathrm{NO}_{2}(\mathrm{~g})$ is favoured at higher temperatures, such as those in a car exhaust:

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

The equilibrium constant, $K_{\mathrm{p}}$, for this reaction is $1.3 \times 10^{+}$at 500 K . What is the value of $K_{\mathrm{c}}$ at 500 K ?
$K_{\mathrm{p}}$ and $K_{\mathrm{c}}$ are related through the equation $K_{\mathrm{p}}=K_{\mathrm{c}}(\mathrm{RT})^{\Delta \mathrm{n}}$ where $\Delta \mathrm{n}$ is the change in the number of moles of gas during the reaction. As three moles go to two moles in the reaction, $\Delta n=-1$ and hence:

$$
\begin{aligned}
& K_{p}=K_{c}(R T)^{-1} \\
& K_{c}=K_{p} \times(\text { RT })=\left(1.3 \times 10^{4}\right) \times(0.08206 \times 500)=5.3 \times 10^{5}
\end{aligned}
$$

$$
K_{\mathrm{c}}=5.3 \times \mathbf{1 0}^{\mathbf{5}}
$$

Using this value and the equilibrium constant for the formation of $\mathrm{NO}(\mathrm{g})$ from the previous page, calculate the value of $K_{\mathrm{c}}$ for the formation of $\mathrm{NO}_{2}(\mathrm{~g})$ from $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{O}_{2}(\mathrm{~g})$ at 500 K according to the following equation.

$$
\mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

From 2007-J-9, $K_{\mathrm{p}}=2.75 \times 10^{-20}$ for the reaction $\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}(\mathrm{g})$. For this reaction, $\Delta \mathrm{n}=0$ and hence $K_{\mathrm{p}}=K_{\mathrm{c}}(\mathrm{RT})^{0}$ or $K_{\mathrm{c}}=K_{\mathrm{p}}$. This reaction and the one above can be combined:

$$
\begin{aligned}
& \mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}(\mathrm{~g}) \quad \mathrm{K}_{\mathrm{c}}=2.75 \times 10^{-20} \\
& \mathbf{2 N O}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad \mathrm{K}_{\mathrm{c}}=5.3 \times 10^{5} \\
& \hline \mathbf{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad \mathrm{K}_{\mathbf{1}}=\left(2.75 \times 10^{-20}\right) \times\left(5.3 \times 10^{s}\right)=1.5 \times 10^{-}
\end{aligned}
$$

$$
K_{\mathrm{c}}=\mathbf{1 . 5} \times \mathbf{1 0}^{-14}
$$

- Give balanced ionic equations for the reactions that occur in each of the following cases.

Potassium metal is added to excess water.

When added to water, potassium produces an alkaline solution and hydrogen gas which is ignited by the exothermicity of the reaction:

$$
2 \mathrm{~K}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{~K}^{+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
$$

Solutions of zinc nitrate and sodium phosphate are mixed.
A white precipitate is produced (Table E2-3 in the Laboratory Manual). The zinc ion has a +2 charge and phosphate, $\mathrm{PO}_{4}{ }^{3-}$, has a $\mathbf{- 2}$ charge:

$$
3 \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{PO}_{4}{ }^{3-}(\mathrm{aq}) \rightarrow \mathrm{Zn}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})
$$

Solid strontium carbonate is dissolved in dilute nitric acid.
Carbonates produce $\mathrm{CO}_{2}(\mathrm{~g})$ when treated with acid:

$$
\mathrm{SrCO}_{3}(\mathbf{s})+2 \mathrm{H}^{+}(\mathbf{a q}) \rightarrow \mathrm{Sr}^{2+}(\mathrm{aq})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathbf{l})
$$

- Explain why the voltage of the lead acid battery $\left(E^{\circ}=2.05 \mathrm{~V}\right)$ decreases when it discharges, whereas the zinc/silver button battery $\left(E^{\circ}=1.6 \mathrm{~V}\right)$ does not.

$$
\begin{gathered}
\mathrm{Pb}(\mathrm{~s}), \mathrm{PbSO}_{4}(\mathrm{~s})\left|\mathrm{H}^{+}(\mathrm{aq}), \mathrm{HSO}_{4}^{-}(\mathrm{aq}) \| \mathrm{H}^{+}(\mathrm{aq}), \mathrm{HSO}_{4}^{-}(\mathrm{aq})\right| \mathrm{PbO}_{2}(\mathrm{~s}), \mathrm{PbSO}_{4}(\mathrm{~s}) \\
\mathrm{Zn}(\mathrm{~s}), \mathrm{ZnO}(\mathrm{~s})\left|\mathrm{OH}^{-}(\mathrm{aq}) \| \mathrm{OH}^{-}(\mathrm{aq})\right| \mathrm{Ag}_{2} \mathrm{O}(\mathrm{~s}), \mathrm{Ag}(\mathrm{~s})
\end{gathered}
$$

The overall reaction for the zinc/silver button battery is:

$$
\mathrm{Zn}(\mathrm{~s})+\mathrm{Ag}_{2} \mathrm{O}(\mathrm{~s}) \rightarrow \mathrm{ZnO}(\mathrm{~s})+2 \mathrm{Ag}(\mathrm{~s})
$$

All components are solids and hence do not enter in to equilibrium constant expression for the reaction or into the Nernst equation for the cell. The voltage will remain constant as concentrations of all products and reactants remains constant.

In contrast, the overall reaction for the lead acid battery is:

$$
\mathbf{P b O}_{2}(\mathbf{s})+\mathbf{P b}(\mathrm{s})+2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{HSO}_{4}^{-}(\mathrm{aq}) \rightarrow 2 \mathrm{PbSO}_{4}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}
$$

Here the concentrations of $\mathrm{H}^{+}(\mathrm{aq})$ and $\mathrm{HSO}_{4}^{-}(\mathrm{aq})$ decrease as the battery discharges and hence the voltage drops.

- If 1.00 tonne $\left(10^{3} \mathrm{~kg}\right)$ of aluminium metal is produced by the electrolysis of molten $\mathrm{Al}_{2} \mathrm{O}_{3}$, how many tonnes of carbon dioxide are emitted by oxidation of the carbon electrodes?

The overall reaction is:

$$
2 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{l})+3 \mathrm{C}(\mathrm{~s}) \rightarrow 4 \mathrm{Al}(\mathrm{~s})+3 \mathrm{CO}_{2}(\mathrm{~g})
$$

3 moles of $\mathrm{CO}_{2}$ are produced for every 4 moles of $\mathrm{Al}(\mathrm{s})$. The atomic mass of aluminium is 26.98 so the amount of aluminium in $10^{3} \mathrm{~kg}=10^{6} \mathrm{~g}$ is:

$$
\text { amount of aluminium }=\frac{\text { mass }}{\text { atomic mass }}=\frac{\left(1.00 \times 10^{6}\right)}{(26.98)}=37100 \mathrm{~mol}
$$

Therefore the amount of $\mathrm{CO}_{2}$ produced is $(3 / 4 \times 37100 \mathrm{~mol})=27800 \mathrm{~mol}$.
The molar mass of $\mathrm{CO}_{2}$ is $(12.01(\mathrm{C}))+(2 \times 16.00)=44.01$. Hence, this amount of $\mathrm{CO}_{2}$ corresponds to a mass of:

$$
\begin{aligned}
\text { mass } & =\text { molar mass } \times \text { number of moles }=(27800) \times(44.01)=1.22 \times 10^{6} \\
& =1.22 \text { tonnes }
\end{aligned}
$$

- The electrolysis of aqueous sodium chloride produces $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{Cl}_{2}(\mathrm{~g})$. Circle the

## 

 choice that correctly finishes each of the following statements about this process.The $\mathrm{Cl}_{2}(\mathrm{~g})$ is produced at the $\qquad$
In the aqueous salt solution, the sodium ions migrate towards the electrode that produces.
As the electrolysis proceeds the pH of the aqueous salt solution.
If the process were being run with a battery, the positive electrode of the battery would be connected to the electrode that produces $\qquad$

| $\underline{\text { anode }}$ | cathode |
| :---: | :---: |
| $\mathrm{Cl}_{2}(\mathrm{~g})$ | $\underline{\mathbf{H}_{2}(\mathbf{g})}$ |
| increases | decreases |
|  |  |
| $\underline{\mathbf{C l}}_{\underline{2}(\mathbf{g})}$ | $\mathrm{H}_{2}(\mathrm{~g})$ |

The two half cells are:

$$
\begin{array}{ll}
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e}^{-} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq}) & \text { reduction (always occurs at the } \\
\text { cathode) } & \\
2 \mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}^{-} & \text {oxidation (always occurs at the anode) }
\end{array}
$$

The cathode is negatively charged so $\mathrm{Na}^{+}(\mathrm{aq})$ migrate to the cathode where $\mathrm{H}_{2} \mathrm{O}$ is preferentially reduced to $\mathbf{H}_{2}(\mathrm{~g})$.
$\mathrm{OH}^{-}(\mathrm{aq})$ is produced at the cathode so the $\mathbf{p H}$ increases.
The anode is positively charged with the positive electrode of the battery is connected to it. $\mathrm{Cl}_{2}(\mathrm{~g})$ is produced at the anode.
