- The cubic form of boron nitride (borazon) is the second-hardest material after diamond and it crystallizes with the structure shown below. The large spheres represent the nitrogen atoms and the smaller spheres represent boron atoms.

From the unit-cell shown above, determine the empirical formula of boron nitride.

There are $\mathbf{N}$ atoms on the corners and on the faces of the unit cell:

- There are 8 N atoms on the corners. These contribute $1 / 8$ to the unit cell giving a total of $8 \times 1 / 8=1 \mathrm{~N}$ atom.
- There are 6 N atoms on the faces. These contribute $1 / 2$ to the unit cell giving a total of $6 \times 1 / 2=3 \mathrm{~N}$ atoms.
- There are a total of $1+3=4 \mathrm{~N}$ atoms in the unit cell.

There are $B$ atoms inside the unit cell:

- There are 4 B atoms completely inside the cell. These contribute only to this unit cell giving a total of $4 \times 1=4 B$ atoms.

The formula is therefore $B_{4} N_{4}$ which simplifies to $B N$.

Answer: BN
Determine the oxidation state of the boron atoms.

Nitrogen has an oxidation number of -III (or -3) to complete its octet. To ensure neutrality, boron must be + III (or +3 ).
Answer: +III (or +3)

ANSWER CONTINUES ON THE NEXT PAGE

The cubic form of boron nitride is more thermally stable in air than diamond. Provide a reasonable explanation for this observation.

Boron and nitrogen have different electronegativities, with $\mathbf{N}$ more electronegative than B. This leads to partial $\delta+$ and $\delta$ - charges on $\mathbf{B}$ and $\mathbf{N}$ respectively. These charges give the bonds partial ionic character and this acts to increase the strength of the bonds.

- A simplified phase diagram for iron is shown below, with the solid part divided into the body-centred cubic (BCC) and face-centred cubic (FCC) phases.

Which form of iron is stable at room temperature and pressure?

BCC form

If molten iron is cooled slowly to around $1200{ }^{\circ} \mathrm{C}$ and then cooled rapidly to room temperature, the FCC form is obtained. Draw arrows on the phase diagram to indicate this process and explain why it leads to the FCC form as a metastable phase.

The slow cooling leads to the most stable form at $1200{ }^{\circ} \mathrm{C}$ - the FCC form. Fast cooling to room temperature does not allow the atoms to re-arrange; they are stuck in the FCC form as considerable re-arrangement is needed to turn this in the BCC form.

The structure is stuck in the FCC arrangement even though BCC is more stable.

The line dividing the BCC and FCC forms is almost, but not quite vertical. Predict which way this line slopes and explain your answer.

BCC is less dense than FCC - the latter is a close packed structure so has the maximum possible density whereas the former is not closed packed.

Applying pressure will favour the more dense structure as it takes up less space. Increasing pressure therefore favours the FCC structure. The line between BCC and FCC has a negative slope ( () ). If the system is on the line and the pressure is increased, the system moves into the FCC region.

- Solution A consists of a 0.050 M aqueous solution of benzoic acid, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$, at $25^{\circ} \mathrm{C}$. Calculate the pH of Solution A. The $\mathrm{p} K_{\mathrm{a}}$ of benzoic acid is 4.20 .

As benzoic acid is a weak acid, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$must be calculated using a reaction table:

|  | $\mathrm{C}_{\mathbf{6}} \mathbf{H}_{\mathbf{5}} \mathbf{\mathrm { COOH }}$ | $\rightleftharpoons$ | $\mathrm{H}^{+}$ | $\mathrm{C}_{\mathbf{6}} \mathrm{H}_{\mathbf{5}} \mathrm{COO}^{-}$ |
| :---: | :---: | :---: | :---: | :---: |
| initial | 0.050 |  | 0 | 0 |
| change | $-x$ |  | $+x$ | $+x$ |
| final | $0.050-x$ |  | $x$ | $x$ |

The equilibrium constant $K_{\mathrm{a}}$ is given by:

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right]}=\frac{x^{2}}{0.050-x}
$$

As $\mathrm{p} K_{\mathrm{a}}=-\log _{10} K_{\mathrm{a}}, K_{\mathrm{a}}=10^{4.20}$ and is very small, $0.050-x \sim 0.050$ and hence:

$$
x^{2}=0.050 \times 10^{-4.2} \quad \text { or } \quad x=1.78 \times 10^{-3} \mathrm{M}=\left[\mathrm{H}^{+}\right]
$$

Hence, the $\mathbf{p H}$ is given by:

$$
\mathbf{p H}=-\log _{10}\left[\mathrm{H}^{+}\right]=-\log _{10}\left(1.78 \times 10^{-3}\right)=2.75
$$

$$
\mathrm{pH}=\mathbf{2 . 7 5}
$$

Other than water, what are the major species present in solution A?
$K_{\mathrm{a}}$ is very small and the equilibrium lies almost completely to the left. The major species present are water and the undissociated acid: $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$

Solution B consists of a 0.050 M aqueous solution of ammonia, $\mathrm{NH}_{3}$, at $25^{\circ} \mathrm{C}$.
Calculate the pH of Solution B. The $\mathrm{p} K_{\mathrm{a}}$ of $\mathrm{NH}_{4}{ }^{+}$is 9.24 .
$\mathrm{NH}_{3}$ is a weak base so $\left[\mathrm{OH}^{-}\right]$must be calculated by considering the equilibrium:

|  | $\mathrm{NH}_{3}$ | $\mathrm{H}_{2} \mathrm{O}$ | $\rightleftharpoons$ | $\mathrm{NH}_{4}{ }^{+}$ | $\mathrm{OH}^{-}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| initial | 0.050 | large |  | 0 | 0 |
| change | $-y$ | negligible |  | $+y$ | $+y$ |
| final | $0.050-y$ | large |  | $y$ | $y$ |

The equilibrium constant $K_{\mathrm{b}}$ is given by:

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}{ }^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=\frac{y^{2}}{(0.050-y)}
$$

For an acid and its conjugate base:

$$
\begin{aligned}
& \mathrm{p} K_{\mathrm{a}}+\mathrm{p} K_{\mathrm{b}}=14.00 \\
& \mathrm{p} K_{\mathrm{b}}=14.00-9.24=4.76
\end{aligned}
$$

As $\mathrm{p} K_{\mathrm{b}}=4.76, K_{\mathrm{b}}=10^{-4.76} . K_{\mathrm{b}}$ is very small so $0.050-\boldsymbol{y} \sim 0.050$ and hence:

$$
y^{2}=0.050 \times 10^{-4.76} \text { or } y=9.32 \times 10^{-4} \mathrm{M}=\left[\mathrm{OH}^{-}\right]
$$

Hence, the pOH is given by:

$$
\mathrm{pOH}=-\log _{10}\left[\mathrm{OH}^{-}\right]=\log _{10}\left[9.32 \times 10^{-4}\right]=3.03
$$

Finally, $\mathbf{p H}+\mathbf{p O H}=14.00$ so

$$
\mathrm{pH}=14.00-3.03=10.97
$$

$$
\mathrm{pH}=\mathbf{1 0 . 9 7}
$$

Other than water, what are the major species present in solution B?
$K_{\mathrm{b}}$ is very small and the equilibrium lies almost completely to the left. The major species present are water and the unprotonated weak base: $\mathbf{N H}_{\mathbf{3}}$

Write the equation for the reaction that occurs when benzoic acid reacts with
$\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$

Write the expression for the equilibrium constant for the reaction of benzoic acid with ammonia?

$$
K=\frac{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(\mathrm{aq})\right]\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(\mathrm{aq})\right]\left[\mathrm{NH}_{3}(\mathbf{a q})\right]}
$$

What is the value of the equilibrium constant for the reaction of benzoic acid with ammonia?

Multiplying the expression above by $\left[\mathrm{H}^{+}\right] /\left[\mathrm{H}^{+}\right]$gives:

$$
\begin{aligned}
K & =\frac{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(\mathrm{aq})\right]\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}_{(\mathrm{aq})][ } \mathrm{NH}_{3}(\mathrm{aq})\right]} \cdot \frac{\left[\mathrm{H}^{+}(\mathrm{aq})\right]}{\left[\mathrm{H}^{+}(\mathrm{aq})\right]} \\
& =\frac{\left[\mathrm{H}^{+}\left(\mathrm{aq}^{2}\right)\right]\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathbf{C O O H}(\mathrm{aq})\right]} \cdot \frac{\left[\mathrm{NH}_{4}+(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]\left[\mathrm{H}^{+}(\mathrm{aq})\right]} \\
& =K_{\mathrm{a}} \times \frac{K_{b}}{\left[\mathrm{H}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}=\frac{K_{\mathrm{a}} \times K_{b}}{K_{\mathrm{w}}} \\
& =\frac{\left(10^{-\mathbf{4 . 2 0}}\right) \times 10^{-4.76}}{\left(10^{-14}\right)}=1.1 \times 10^{5}
\end{aligned}
$$

Answer: $\mathbf{1 . 1} \times \mathbf{1 0}^{\mathbf{5}}$
What are the major species in the solution that results from dissolving equimolar amounts of benzoic acid and ammonia in water?

The equilibrium strong favours products so the major species are:
$\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CO}_{2}{ }^{-}(\mathrm{aq}), \mathrm{NH}_{4}{ }^{+}(\mathrm{aq}), \mathrm{H}_{2} \mathrm{O}$ (I)
THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- The salt calcium oxalate, $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$, is sparingly soluble. Write down the chemical equation for its dissolution in water and the expression for $K_{\mathrm{sp}}$.

$$
\begin{aligned}
& \mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) \rightarrow \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]
\end{aligned}
$$

What is the molar solubility of calcium oxalate? $K_{\text {sp }}=2.3 \times 10^{-9}$

If $\boldsymbol{x}$ mol of the salt dissolves in one litre, then the molar solubility is $\boldsymbol{x}$ M. If $\boldsymbol{x}$ mol dissolves in one litre then $\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]=\boldsymbol{x} \mathbf{M}$ and $\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]=\boldsymbol{x} \mathbf{M}$.

$$
\begin{aligned}
& K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]=(x)(x)=x^{2}=2.3 \times 10^{-9} \\
& x=4.8 \times 10^{-5} \mathrm{~mol} \mathrm{~L}^{-1}
\end{aligned}
$$

Answer: $\mathbf{4 . 8 \times 1 0 ^ { - 5 }} \mathbf{~ m o l ~ L}^{-1}$
If additional calcium oxalate is added to a saturated solution, what is the effect on $\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]$ ?

A saturated solid has the maximum possible dissolution. Adding additional solid has no effect on the equilibrium and so no effect on $\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]$.

Following blood donation, a solution of sodium oxalate is added to remove $\mathrm{Ca}^{2+}(\mathrm{aq})$ ions which cause the blood to clot. The concentration of $\mathrm{Ca}^{2+}(\mathrm{aq})$ ions in blood is $9.7 \times 10^{-5} \mathrm{~g} \mathrm{~mL}^{-1}$. If 100.0 mL of $0.1550 \mathrm{M} \mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ is added to 100.0 mL of blood, what will be the concentration (in $\mathrm{mol} \mathrm{L}^{-1}$ ) of $\mathrm{Ca}^{2+}$ ions remaining in the blood?

The amount of $\mathrm{Ca}^{2+}$ present in 100.0 mL is $9.7 \times 10^{-3} \mathrm{~g}$. As its molar mass is $\mathbf{4 0 . 0 8}$ $\mathrm{g} \mathrm{mol}^{-1}$, this corresponds to:

$$
\begin{aligned}
\text { number of moles } & =\text { mass } / \text { molar mass }= \\
& =\left(9.7 \times 10^{-3} \mathrm{~g}\right) /\left(\mathbf{4 0 . 0 8} \mathrm{g} \mathrm{~mol}^{-1}\right)=2.4 \times 10^{-4} \mathrm{~mol}
\end{aligned}
$$

The number of moles of $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})$ added is:
number of moles $=$ concentration $\times$ volume

$$
=\left(0.1550 \mathrm{~mol} \mathrm{~L}^{-1}\right) \times(0.1000 \mathrm{~L})=0.01550 \mathrm{~mol}
$$

The amount of $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$ is much larger than the amount of $\mathrm{Ca}^{2+}$ present so precipitation of $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}(\mathrm{s})$ does not reduce the $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$ significantly.

When the oxalate is added to the blood, the total volume increases to $(100.0+$ $100.0) \mathrm{mL}=200.0 \mathrm{~mL}$. The concentration of $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})$ is now:

## ANSWER CONTINUES ON THE NEXT PAGE

concentration $=$ number of moles $/$ volume

$$
=(0.01550 \mathrm{~mol}) /(0.2000 \mathrm{~L})=0.0775 \mathrm{~mol} \mathrm{~L}^{-1}
$$

Using $K_{\text {sp }}=\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]$ :

$$
\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]=K_{\mathrm{sp}} /\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]=\left(2.3 \times 10^{-9} / 0.0775\right) \mathrm{M}=3.0 \times 10^{-8} \mathrm{M}
$$

Answer: $\mathbf{3 . 0} \times \mathbf{1 0}^{-8} \mathbf{M}$

- The structure below represents the active site in carbonic anhydrase, which features a $\mathrm{Zn}^{2+}$ ion bonded to 3 histidine residues and a water molecule.

The $\mathrm{p} K_{\mathrm{a}}$ of uncoordinated water is 15.7 , but the $\mathrm{p} K_{\mathrm{a}}$ of the water ligand in carbonic anhydrase is around 7. Suggest an explanation for this large change.

The high charge on the $\mathbf{Z n}^{\mathbf{2 +}}$ ion draws electron density out of the $\mathbf{O}-\mathbf{H}$ bonds in the water molecule. This weakens the $\mathrm{O}-\mathrm{H}$ so the $\mathrm{H}^{+}$is more likely to leave.
The water in carbonic anhydrase is therefore more acidic, as shown by the large decrease in $\mathrm{p} K_{\mathrm{a}}$.

When studying zinc-containing metalloenzymes, chemists often replace $\mathrm{Zn}^{2+}$ with $\mathrm{Co}^{2+}$. Using the box notation to represent atomic orbitals, work out how many unpaired electrons are present in the $\mathrm{Zn}^{2+}$ and $\mathrm{Co}^{2+}$ ions.

$$
\begin{aligned}
& \mathbf{Z n}^{2+}, \mathbf{3} d^{10} \\
& \mathbf{C o}^{2+}, \mathbf{3} d^{7}
\end{aligned}
$$

| $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow \downarrow$ |
| :---: | :---: | :---: | :---: | :---: |
| $\uparrow \downarrow$ | $\uparrow \downarrow$ | $\uparrow$ | $\uparrow$ | $\uparrow$ |

$\mathbf{Z n}^{2+}$ has 0 unpaired $d$ electrons, $\mathrm{Co}^{2+}$ has $\mathbf{3}$ unpaired $d$ electrons. $\mathrm{Co}^{2+}$ is therefore paramagnetic and will be attracted by a magnetic field.

Suggest why it is useful to replace $\mathrm{Zn}^{2+}$ with $\mathrm{Co}^{2+}$ when studying the nature of the active site in carbonic anhydrase.

The ions have similar radii so the properties of natural carbonic anhydrase and the version with cobalt replacing zinc should have similar biological properties. The unpaired electrons on $\mathrm{Co}^{2+}$ however mean that it is paramagnetic and the magnetism can be used to study the active site.

Suggest two differences in the chemistry of $\mathrm{Zn}^{2+}$ and $\mathrm{Co}^{2+}$ ions that may affect the reactivity of the cobalt-containing enzyme.

Zinc only forms +2 ions but cobalt forms +2 and +3 . The cobalt-containing enzyme may be susceptible to oxidation.
$\mathbf{Z n}^{2+}$ tends to form 4-coordinate tetrahedral complexes but $\mathbf{C o}^{\mathbf{2 +}}$ is slightly larger and often forms $\mathbf{6}$-coordinate octahedral complexes. The metal ion may change its coordination by bonding extra ligands.

- Complete the following table.
STARTING MATERIAL REAGENTS/CONDITIONS
- Draw the structure of (S)-pent-4-en-2-ol.

When $(S)$-pent-4-en-2-ol reacts with bromine, $\mathrm{Br}_{2}$, two stereoisomers are formed. Draw the structure of both products.

- Draw the structure of the organic product(s) formed when each of the following compounds is treated with 4 M sodium hydroxide. The first reaction requires heating.
Compound
- The elimination of $\mathrm{H}_{2} \mathrm{O}$ from alcohol $\mathbf{A}$ can form the isomeric alkenes $\mathbf{B}$ and $\mathbf{C}$. Elimination of HBr from the alkyl halide $\mathbf{D}$ can generate the same two alkenes.

Assign the absolute configuration of alcohol $\mathbf{A}$. Show your working.

(R)

(S)

There are 2 chiral centres. On the diagram on the left, the priorities are as shown and are in an $(R)$ configuration. On the diagram on the right, the priorities are in an $(S)$ arrangement.

Name compound B fully.

## (Z)-3-methylpent-2-ene

A diastereoisomer of $\mathbf{B}$ is also formed in these reactions. Draw the enantiomer of $\mathbf{A}$ and the diastereoisomer of $\mathbf{B}$.
enantiomer of $\mathbf{A}$

ANSWERS CONTINUES ON THE NEXT PAGE

Propose a mechanism for the formation of $\mathbf{B}$ from $\mathbf{A}$ under the conditions shown. Use curly arrows and draw the structures of any intermediates.

THIS QUESTION CONTINUES ON THE NEXT PAGE.

Explain why compound $\mathbf{C}$ is the minor product of this reaction.
$\mathbf{C}$ has the new $\mathbf{C}=\mathbf{C}$ bond with fewer substituents. This is an example of Zeitsev's rule: the more substituted alkene is more thermodynamically stable.

Propose a mechanism for the formation of $\mathbf{C}$ from $\mathbf{D}$ under the conditions shown. Use curly arrows and draw the structures of any intermediates.

Compound $\mathbf{C}$ is the major product formed from $\mathbf{D}$ under these conditions. What would be the major product if the enantiomer of $\mathbf{D}$ were exposed to the same reaction conditions?

THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- Propene can be converted into 1,2-dimethyl-1-phenylpropene using a sequence of 6 reactions. Demonstrate your knowledge of Grignard reactions by suggesting a plausible sequence. Make sure you draw the correct structure for each intemediate product and clearly indicate the reagent(s) required for each reaction. The following list of suggested reagents is sufficient to accomplish all necessary reactions, but you may use other reagents if you wish. One of the intermediates is shown for you.

Suggested reagents:

HBr dilute HCl
$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7} / \mathrm{H}^{\oplus}$
conc. HCl
Mg
$\mathrm{CH}_{3} \mathrm{MgBr}$
