

CHEM1109 Worksheet 9 – Answers to Critical Thinking Questions

The worksheets are available in the tutorials and form an integral part of the learning outcomes and experience for this unit.

Model 1: Reduction Potentials

- Oxidising agents are themselves reduced – the strongest oxidising agent is the most easily reduced. This is $\text{Ag}^+(\text{aq})$ as it has the most positive E_{red}° value (it has the strongest attraction to electrons).
- Reaction (1) will remain a reduction. Reaction (2) will reverse to become an oxidation, as $\text{Ag}^+(\text{aq})$ is the strongest oxidising agent.
- Reaction (3) will remain a reduction. Reaction 4 will reverse to become an oxidation as $\text{Zn}^{2+}(\text{aq})$ is the stronger reducing agent. It does not matter that they are both negative as it is the *difference* between the two E_{red}° values which determines the reaction.

Model 2: Voltaic Cells

- The Zn/Zn^{2+} half reaction is proceeding as an oxidation as it has a *lower* E_{red}° value than that for Cu^{2+}/Cu . When we flip a reduction to an oxidation, we reverse the sign of the potential.
- The zinc electrode will *lose* mass and the tin electrode will *gain* mass.
- Oxidation (always) takes place at the anode. Reduction (always) takes place at the cathode
- (b) Electrons flow through the wire, from the zinc electrode towards the tin electrode.
- The anode is negative and the cathode is positive.
- $\text{SO}_4^{2-}(\text{aq})$ moves into the zinc half cell (as cations are being made in the oxidation reaction in this cell). $\text{Na}^+(\text{aq})$ moves into the tin half cell (as cations are being lost in this cell).
- Cathode - reduction: $\text{Ag}^+(\text{aq}) + \text{e}^- \rightarrow \text{Ag}(\text{s})$. Anode - oxidation: $\text{Cu}(\text{s}) \rightarrow \text{Cu}^{2+}(\text{aq}) + 2\text{e}^-$
 $E_{\text{cell}}^{\circ} = [0.80 + (-0.34)] \text{ V} = +0.47 \text{ V}$
- Cathode - reduction: $\text{Cu}^{2+}(\text{aq}) + 2\text{e}^- \rightarrow \text{Cu}(\text{s})$. Anode - oxidation: $\text{Sn}(\text{s}) \rightarrow \text{Sn}^{2+}(\text{aq}) + 2\text{e}^-$
 $E_{\text{cell}}^{\circ} = [0.34 + 0.14] \text{ V} = +0.48 \text{ V}$
- Cathode - reduction: $\text{Sn}^{2+}(\text{aq}) + 2\text{e}^- \rightarrow \text{Sn}(\text{s})$. Anode -oxidation: $\text{Zn}(\text{s}) \rightarrow \text{Zn}^{2+}(\text{aq}) + 2\text{e}^-$
 $E_{\text{cell}}^{\circ} = [-0.14 + 0.76] \text{ V} = +0.62 \text{ V}$
- Couple the cells with (i) the most positive and (ii) the least positive (or most negative) reduction potentials. The latter is reversed to become the oxidation reaction.
 $\text{Ag}^+(\text{aq}) + \text{e}^- \rightarrow \text{Ag}(\text{s})$ and $\text{Zn}(\text{s}) \rightarrow \text{Zn}^{2+}(\text{aq}) + 2\text{e}^-$; $E_{\text{cell}}^{\circ} = +1.56 \text{ V}$
- (a) $\text{NAD}^+ + \text{HCOO}^- \rightarrow \text{NADH} + \text{CO}_2$ $E^{\circ} = (-0.105 + 0.20) \text{ V} = +0.10 \text{ V}$
NAD is reduced.
(b) $\text{O}_2 + \text{H}^+ + \text{NADH} \rightarrow \text{H}_2\text{O}_2 + \text{NAD}^+$ $E^{\circ} = (+0.69 + 0.105) \text{ V} = +0.80 \text{ V}$
NAD is oxidised.
