- Copper oxide is used as a photovoltaic material in solar cells and it crystallizes with the structure shown below. The large white spheres represent the oxygen atoms and the smaller black spheres represent copper atoms.

How many unit cells are represented in the above diagram? Explain your answer.

There are 4 unit cells represented.
A unit cell is the simplest repeating unit of a lattice. Each of the 4 cubes are identical and translation of any one of them will generate the overall structure.

From the solid-state structure shown above, determine the empirical formula for copper oxide.

There are $\mathbf{8} \mathbf{O}$ on the corners plus $\mathbf{1 O}$ in the centre. The $O$ on the corners are shared with 8 other cells so contribute $1 / 8$ to the cell. The $O$ at the centre is unshared so contributes only to this cell. The net contribution is $\mathbf{8 \times 1 / 8}+\mathbf{1 = 2}$.

The $4 \mathbf{C u}$ are completely within the cell so only contribute to this cell. The net contribution from Cu is 4 .

## With a Cu: O ratio of $4: 2$, the formula is $\mathrm{Cu}_{2} \mathrm{O}$.

What is the oxidation state of copper in this compound?

With $\mathbf{O}^{2-}$, it must be $\mathbf{C u}(\mathrm{I})(\mathrm{i} . \mathrm{e}+1)$.

Use the box notation to predict whether the copper ions are paramagnetic.
$\mathrm{Cu}^{+}$has 10 electrons in its $3 d$ subshell. They are all paired as shown, so $\mathrm{Cu}^{+}$is diamagnetic, not paramagnetic.

ANSWER CONTINUES ON THE NEXT PAGE

Silver oxide is another Group 11 metal oxide and its solid-state structure is identical to that of copper oxide even though the ionic radius for the copper ion (118 pm) is smaller than that of the silver ion ( 139 pm ). Account for this observation.

The anionic radius of $\mathrm{O}^{\mathbf{2 -}}$ is the main factor determining the solid state structure of the oxides. The cations $\left(\mathrm{Ag}^{+}\right.$or $\left.\mathrm{Cu}^{+}\right)$fit in the holes within the $\mathrm{O}^{2-}$ lattice.

- $\mathrm{K}_{2}\left[\mathrm{Re}_{2} \mathrm{Cl}_{8}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ is an historically important example of a metal-metal bonded complex. Name the complex by using standard IUPAC nomenclature.
potassium octachloridodirhenate(III)-2-water
What is the oxidation state of Re in this complex?
III or +3
4
$\mathrm{K}_{2}\left[\mathrm{Re}_{2} \mathrm{Cl}_{8}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ possesses an extremely short $\mathrm{Re}-\mathrm{Re}$ bond ( 224 pm ), much shorter than the bonding distance between Re atoms in Re metal (274 pm)! Propose a reasonable explanation for the very short Re-Re bond length in the complex by adding $d$-electrons into the (partial) MO scheme shown below. Determine the bond order for the metal-metal bond and draw a structure for the complex.

Reduction of the Re complex by one electron gives rise to a paramagnetic species in which the Re-Re distance increases significantly. Propose a reasonable hypothesis for the bond-lengthening phenomenon.

Reduction is the gain of 1 electron. This is added to the lowest available orbitals (the LUMO): the $\boldsymbol{\delta}^{*}$ anti-bonding orbital to give a paramagnetic species.

This reduces the bond order from 4.0 to 3.5, thus weakening and lengthening the Re-Re bond.

- Boric acid, $\mathrm{B}(\mathrm{OH})_{3}$, is a weak acid $\left(\mathrm{p} K_{\mathrm{a}}=9.24\right)$ that is used as a mild antiseptic and eye wash. Unusually, the Lewis acidity of the compound accounts for its Brønsted acidity. By using an appropriate chemical equation, show how this compound acts as a Brønsted acid in aqueous solution.

The boron atom in $\mathrm{B}(\mathrm{OH})_{3}$ is electron deficient: it has 6 rather than 8 electrons in its valence shell. It acts as a Lewis acid by readily accepting the lone pair from the oxygen in a water molecule to go from $s p^{2}$ to $s p^{3}$ hybridisation.

Solution A consists of a 0.40 M aqueous solution of boric acid at $25^{\circ} \mathrm{C}$. Calculate the pH of Solution A.

As boric is a weak acid, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$must be calculated using a reaction table $\left(\operatorname{acid}=\mathrm{B}(\mathrm{OH})_{3}\right.$ and base $\left.=\mathrm{B}(\mathrm{OH})_{2}{ }^{-}\right)$

|  | acid | $\mathbf{H}_{2} \mathbf{O}$ | $\rightleftharpoons$ | $\mathbf{H}_{3} \mathbf{O}^{+}$ | base |
| :--- | :--- | :--- | :--- | :--- | :--- |
| initial | 0.40 | large |  | 0 | 0 |
| change | $-x$ | negligible |  | $+x$ | $+x$ |
| final | $0.40-x$ | large |  | $x$ | $x$ |

The equilibrium constant $K_{\mathrm{a}}$ is given by: $K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right][\text {base }]}{[\text { acid }]}=\frac{x^{2}}{0.40-x}$
As $\mathrm{p} K_{\mathrm{a}}=-\log _{10} K_{\mathrm{a}}, K_{\mathrm{a}}=10^{9.24}$ and is very small, $0.40-x \sim 0.40$ and hence:

$$
x^{2}=0.40 \times 10^{-9.24} \quad \text { or } \quad x=1.52 \times 10^{-5} M=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]
$$

Hence, the $\mathbf{p H}$ is given by:

$$
\mathrm{pH}=-\log _{10}\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log _{10}\left(1.52 \times 10^{-5}\right)=4.82
$$

$$
\mathrm{pH}=\mathbf{4 . 8 2}
$$

At $25^{\circ} \mathrm{C}, 1.00 \mathrm{~L}$ of Solution B consists of 101.8 g of $\mathrm{NaB}(\mathrm{OH})_{4}$ dissolved in water. Calculate the pH of Solution B.

The molar mass of $\mathrm{NaB}(\mathrm{OH})_{3}$ is:

$$
\begin{aligned}
\text { molar mass } & =[22.99(\mathrm{Na})+10.81(\mathrm{~B})+4(16.00(\mathrm{O})+1.008(\mathrm{H}))] \mathrm{g} \mathrm{~mol}^{-1} \\
& =101.83 \mathrm{~g} \mathrm{~mol}^{-1}
\end{aligned}
$$

## ANSWER CONTINUES ON THE PAGE

A mass of 101.8 g therefore corresponds to:

$$
\text { number of moles }=\text { mass } / \text { molar mass }=101.8 \mathrm{~g} /\left(101.83 \mathrm{~g} \mathrm{~mol}^{-1}\right)=1.000 \mathrm{~mol}
$$

A 1.00 L solution contains this amount has a concentration of 1.00 M .
As it is a weak base, $\left[\mathrm{OH}^{-}\right]$must be calculated by considering the equilibrium:

|  | base | $\mathrm{H}_{2} \mathrm{O}$ | $\rightleftharpoons$ | acid | $\mathrm{OH}^{-}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| initial | 1.00 | large |  | 0 | 0 |
| change | $-y$ | negligible |  | $+y$ | $+y$ |
| final | $1.00-y$ | large |  | $y$ | $y$ |

The equilibrium constant $K_{\mathrm{b}}$ is given by:

$$
K_{\mathrm{b}}=\frac{[\mathrm{acid}]\left[\mathrm{OH}^{-}\right]}{[\text {base }]}=\frac{y^{2}}{(1.00-y)}
$$

For an acid and its conjugate base:

$$
\begin{aligned}
& \mathrm{p} K_{\mathrm{a}}+\mathrm{p} K_{\mathrm{b}}=14.00 \\
& \mathrm{p} K_{\mathrm{b}}=14.00-9.24=4.76
\end{aligned}
$$

As $\mathrm{p} K_{\mathrm{b}}=4.76, K_{\mathrm{b}}=10^{-4.76}$. $K_{\mathrm{b}}$ is very small so $1.00-y \sim 1.00$ and hence:

$$
y^{2}=1.00 \times 10^{-4.76} \text { or } y=0.00417 \mathrm{M}=\left[\mathrm{OH}^{-}\right]
$$

Hence, the pOH is given by:

$$
\mathrm{pOH}=-\log _{10}\left[\mathrm{OH}^{-}\right]=\log _{10}[0.00417]=2.38
$$

Finally, $\mathbf{p H}+\mathbf{p O H}=\mathbf{1 4 . 0 0}$ so

$$
\mathrm{pH}=14.00-2.38=11.62
$$

$$
\mathrm{pH}=\mathbf{1 1 . 6 2}
$$

Using both Solutions A and B, calculate the volumes (mL) required to prepare a 1.0 L solution with a $\mathrm{pH}=8.00$.

The ratio of acid to conjugate base needed can be calculated using the
Henderson-Hasselbalch equation, $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{[\text { base }]}{[\text { acid }]}$ :

$$
8.00=9.24+\log \frac{[\text { base }]}{[\text { acid }]} \text { so } \frac{[\text { base }]}{[\text { acid }]}=10^{-1.24}=0.0575
$$

ANSWER CONTINUES ON THE PAGE

A volume $V_{\mathrm{a}}$ of the acid and $V_{\mathrm{b}}$ of base are added together to give a solution with a total volume of 1.0 L so:

$$
V_{\mathrm{a}}+V_{\mathrm{b}}=1.0 \mathrm{~L}
$$

Using $c_{1} V_{1}=c_{2} V_{2}$, this mixing reduces the concentration of both:
acid: $(0.40 \mathrm{M}) \times V_{\mathrm{a}}=c_{\mathrm{acid}} \times(1.0 \mathrm{~L}) \quad$ so $V_{\mathrm{a}}=2.5 \times c_{\text {acid }}$
base: $(1.00 \mathrm{M}) \times V_{\mathrm{b}}=c_{\text {base }} \times(1.0 \mathrm{~L}) \quad$ so $V_{\mathrm{b}}=1.0 \times c_{\text {base }}$
Using the concentration ratio from the Henderson-Hasselbalch equation above, the ratio of the volumes needed is therefore:

$$
V_{\mathrm{b}} / V_{\mathrm{a}}=(1.0 / 2.5) \times c_{\text {base }} / c_{\text {acid }}=(1.0 / 2.5) \times 0.0575=0.023
$$

or

$$
V_{\mathrm{b}}=0.023 \times V_{\mathrm{a}}
$$

From above, $V_{\mathrm{a}}+\boldsymbol{V}_{\mathrm{b}}=1.0 \mathrm{~L}$ so:

$$
\begin{aligned}
& V_{\mathrm{a}}+\left(0.023 \times V_{\mathrm{a}}\right)=1.0 \mathrm{~L} \\
& 1.023 V_{\mathrm{a}}=1.0 \mathrm{~L} \\
& V_{\mathrm{a}}=0.980 \mathrm{~L}
\end{aligned}
$$

Hence, $V_{b}=0.020 \mathrm{~L}$.

- What is the solubility of $\mathrm{Cu}(\mathrm{OH})_{2}$ in $\mathrm{mol} \mathrm{L}^{-1}$ ? $K_{\mathrm{sp}}\left(\mathrm{Cu}(\mathrm{OH})_{2}\right)$ is $1.6 \times 10^{-19}$ at $25^{\circ} \mathrm{C}$.

The dissolution reaction and associated solubility product are:

$$
\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \quad K_{\mathrm{sp}}=\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}
$$

If $x$ mol dissolve in one litre, $\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]=x \mathrm{M}$ and $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=2 x$. Hence:

$$
\begin{aligned}
& K_{\mathrm{sp}}=(x)(2 x)^{2}=4 x^{3}=1.6 \times 10^{-19} \\
& x=3.4 \times 10^{-7} \mathrm{M}
\end{aligned}
$$

## Answer: $\mathbf{3 . 4} \times \mathbf{1 0}^{-7} \mathbf{M}$

The overall formation constant for $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ is $1.0 \times 10^{13}$. Write the equation for the reaction of $\mathrm{Cu}^{2+}$ ions with excess ammonia solution.

$$
\mathrm{Cu}^{2+}(\mathrm{aq})+4 \mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}(\mathrm{aq})
$$

Calculate the value of the equilibrium constant for the following reaction.

$$
\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s})+4 \mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

This reaction can be considered to occur via (i) $\mathbf{C u ( O H})_{2}$ dissolving followed by (ii) the $\mathbf{C u}^{2+}(\mathrm{aq})$ ions that form being complexed by ammonia.

For the formation of $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{\mathbf{2 +}}$, the equilibrium constant is:

$$
K_{\text {stab }}=\frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=1.0 \times 10^{13}
$$

For the reaction of $\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s})$ with $\mathrm{NH}_{3}(\mathrm{aq})$, the equilibrium constant is:

$$
K=\frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}}{\left[\mathrm{NH}_{3}\right]^{4}}
$$

To obtain $K, K_{\text {sp }}$ is multiplied by $K_{\text {stab }}$ :

$$
\begin{aligned}
K & =K_{\text {sp }} \times K_{\text {stab }} \\
& =\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right)\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2} \times \frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=\frac{\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}}{\left[\mathrm{NH}_{3}\right]^{4}} \\
& =\left(1.6 \times 10^{-19}\right) \times\left(1.0 \times \mathbf{1 0}^{13}\right)=1.6 \times 10^{-6}
\end{aligned}
$$

Would you expect $\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s})$ to dissolve in $1 \mathrm{M} \mathrm{NH}_{3}$ solution? Briefly explain your answer.

No. Equilibrium constant $K$ is very small so the reaction lies heavily in favour of reactants.

- The diagram below shows the phase diagram of sulfur. Note that 'rhombic' and 'monoclinic' refer to two different crystalline forms of the element.

Determine the number of triple points for sulfur and indicate which species are present at each of the triple points.

There are 3 triple points:

- rhombic, monoclinic and vapour (at $95.31{ }^{\circ} \mathrm{C}$ and $5.1 \times 10^{-6} \mathrm{~atm}$ );
- monoclinic, liquid and vapour (at $115.18{ }^{\circ} \mathrm{C}$ and $3.2 \times 10^{-5} \mathrm{~atm}$ );
- rhombic, monoclinic and liquid (at $153{ }^{\circ} \mathrm{C}$ and 1420 atm );

Which crystalline form of sulfur is predicted to be more dense? Briefly explain your answer.

The rhombic allotrope is denser. If you start in the monoclinic region and increase the pressure at constant temperature (i.e. draw a vertical line upwards) you move into the rhombic region. Rhombic is thus the more stable form at higher pressures, so must be denser.
"Plastic" sulfur is a tough elastic substance that is formed when molten sulfur (m.p. $=115.2^{\circ} \mathrm{C}$ ) is poured into cold water. On standing, it slowly crystallizes. Predict which crystalline form is formed at room temperature and pressure. Also, explain why "plastic" sulfur is not shown on the above phase diagram.

Rhombic sulfur is formed. Plastic sulfur is not shown as it is a metastable state and changes into a more stable state over time. Phase diagrams only show stable states that are in equilibrium with other stable states. There are no conditions of temperature and pressure in which plastic sulfur is in equilibrium with another state of sulfur, so it does not appear on the phase diagram.
Based on the information provided, it is reasonable to assume that plastic sulfur is a compound formed by reaction of water with sulfur or some form of sulfur involving water in its crystal structure. Arguing that, and that the phase diagram for sulfur only shows pure forms of sulfur, was also awarded full marks.

- Addition of HBr to the isomer of 2-pentene shown below gives 3 isomeric products, $\mathbf{A}, \mathbf{B}$ and $\mathbf{C}$, in an approximate ratio of 50:25:25 respectively.

Draw the three products $\mathbf{A}, \mathbf{B}$ and $\mathbf{C}$.

Explain the ratio of products observed.

The double bond is equally substituted, so attack of the electrophile $\mathbf{H}^{+}$is equally likely at C2 or C3. The carbocations at C3 and C2 should therefore be formed in equal amounts. Subsequent attack of the trigonal planar carbocation by $\mathrm{Br}^{-}$is equally likely from above or below the molecule. Attack at C3 produces only one compound. Attack at $\mathbf{C} 2$ produces either the $(R)$ - or ( $S$ )- enantiomer in equal amounts.

What is the isomeric relationship between $\mathbf{A}$ and $\mathbf{B}$ ?
What is the isomeric relationship between $\mathbf{B}$ and $\mathbf{C}$ ?

| Constitutional isomers |
| :--- |
| Enantiomers |

Assign the stereochemistry of the starting material isomer. Show your working.

The higher priority groups are methyl (at C2) and ethyl (at C3). These are on opposite sides of the double bond and hence the molecule has ( $E$ ) stereochemistry.

Draw the other configurational isomer of 2-pentene and assign its stereochemistry.

(Z)- isomer

What product(s) would you expect from the addition of HBr to this stereoisomer, and in what ratio?

Same ratio as for the $(E)$ isomer, i.e. $\mathbf{5 0 \%} \mathbf{A}, \mathbf{2 5 \%} \mathbf{B , 2 5 \%}$ C.

- Consider the amine $\mathbf{D}$, imine $\mathbf{E}$ and nitrile $\mathbf{F}$ shown below. Draw any lone pairs of electrons that are required to complete the structures.

D

F

What is the hybridisation at $N$ in compound $\mathbf{D}$ ?
What is the hybridisation at $N$ in compound $\mathbf{E}$ ?

| $s p^{3}$ |
| :--- |
| $s p^{2}$ |
| $s p$ |

Which of these compounds is the most basic? Why?
D is most basic. The $\boldsymbol{s}^{\mathbf{3}}$ hybridised $\mathbf{N}$ has more $\boldsymbol{p}$ orbital character (75\%) compared to $s p^{2}(67 \%)$ or $s p(50 \%)$. D therefore has a more diffuse lone pair that is more available for protonation.

THE REMAINDER OF THIS PAGE IS FOR ROUGH WORKING ONLY.

- Consider the following reaction sequences beginning with the secondary alcohol, $\mathbf{G}$.

 $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}$ (Step ii)

Suggest structures for compounds $\mathbf{H}-\mathbf{M}$ in the reaction sequences above.

| H |  | I |  | J |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
| K |  | L |  | M |  |
|  |  |  |  |  |  |

What approximate ratio $\mathbf{H}$ : I do you expect? Why?
$1: 1$. Both products are formed from a common carbocation intermediate.
There is no real preference for which $\mathbf{H}^{+}$will be lost as both products (H and I) have the same degree of substitution (Saytsev's rule).

What type of reaction is occurring in Step i?
What type of reaction is occurring in Step ii?
What type of reaction is occurring in Step iii?
What type of reaction is occurring in Step iv?

- The hydroxide anion can react with chloroethane via a mechanism that is abbreviated $S_{N} 2$, as shown below. Add curly arrows to the reaction scheme to complete a mechanism for this reaction.

Explain what each part of the abbreviation $\mathrm{S}_{\mathrm{N}} 2$ means.

## $S=$ substitution

${ }_{N}=$ nucleophilic
2 = bimolecular
The hydroxide anion undergoes an apparently similar reaction with ethanoyl chloride:

Draw a mechanism (using curly arrows) for this reaction, thereby demonstrating how it is fundamentally different to the reaction of chloroethane above.

In each of these reactions, a full molecular orbital of the hydroxide anion (the HOMO) interacts with an empty molecular orbital of the organic halogen compound (the LUMO).

Which orbital is the LUMO in chloroethane?
Which orbital is the LUMO in ethanoyl chloride?

| $\sigma^{*}{ }_{\mathrm{C}-\mathrm{Cl}}$ |
| :---: |
| $\pi^{*} \mathrm{C}=\mathrm{O}$ |

- A step-by-step mechanism for the formation of an acetal from a hemiacetal is outlined below. Demonstrate your understanding of reaction mechanisms by adding curly arrows to complete this mechanism.
Note: you don't need to have seen this mechanism before to answer this question.

Overall, what type of reaction $(\mathbf{P} \rightarrow \mathbf{Q})$ is shown here?

## Substitution

Identify one nucleophile and one electrophile in the scheme above.

| nucleophile | electrophile |
| :--- | :--- |
| $\mathbf{H}_{2} \mathbf{O}$ or $\mathbf{C H}_{3} \mathbf{O H}$ | $\mathrm{H}^{\oplus}$ or |
